#### Abstract

In our three previous papers [1, 2, 3], referred to as I, II and III. In I and II, our new expression for the static dielectric constant, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathrm{r}_{\mathrm{d}(\mathrm{a})}$ being the donor (acceptor) $\mathrm{d}(\mathrm{a})$-radius, was determined by using an effective Bohr model, suggesting that, for an increasing $\mathrm{r}_{\mathrm{d}(\mathrm{a})}, \varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, due to such the impurity size effect, decreases, and affecting strongly the critical d(a)-density in the metal-insulator transition (MIT), $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, determined by Eq. (3), and also the optical coefficients, given in the $\mathrm{n}(\mathrm{p})$-type degenerate Si crystal, at low temperature T and high $\mathrm{d}(\mathrm{a})$-density N , according to the reduced Fermi energy $\xi_{\mathrm{n}(\mathrm{p})}(\geqq 1)$, since those coefficients are expressed in terms of $\left(\mathrm{E}^{*} \equiv E-\right.$ $\left.\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\right)^{2}$. Here, $\mathrm{E}^{*}$ is the effective photon energy, E is the photon energy and $\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}$ is the band gap, which can be equal to the intrinsic band gap $\mathbb{E}_{\text {gni }(g \mathrm{gi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, and optical band gap $\mathbb{E}_{\mathrm{gn1} 1 \mathrm{gp} 1)}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right)$, as those defined in Eq. (5), noting that $\mathrm{N}^{*}$ is the effective $\mathrm{d}(\mathrm{a})$-density, defined by: $\mathrm{N}^{*} \equiv \mathrm{~N}-\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, being the effective density of free electrons (holes), given in the parabolic conduction (valence) bands of the $n(p)$-type degenerate $d(a)$-Si crystals. Then, using the same physical model and same mathematical methods and taking into account the corrected values of energy-band-structure parameters, all the numerical results of the optical coefficients, obtained in III, are now revised and performed, giving rise to some important concluding remarks, as follows. (i)The physical MIT-condition for N , is found to be given by: $\mathrm{N}^{*} \equiv \mathrm{~N}-\mathrm{N}_{\mathrm{CDn}(\operatorname{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$ or $\mathrm{N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, which can be explained by the density of electrons (holes) localized in the exponential conduction(valence)-band tails, $N_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, determined in Eq. (21), with a precision of the order of $10^{-5}$, as given in Table 1. (ii) By basing on correct asymptotic behaviors of the refraction index $n$ and extinction coefficient $\kappa$, as those proposed in Equations $(28,29)$, we have investigated all the optical coefficients, being determined in Equations $(24,25,28,29)$,

and then their numerical results given in different physical conditions have been tabulated and discussed in Tables $2 \mathrm{a}(\mathrm{b}$, c), $3 \mathrm{a}(\mathrm{b}, \mathrm{c}), 4 \mathrm{n}(\mathrm{p}), 5 \mathrm{n}(\mathrm{p})$, and $6 \mathrm{n}(\mathrm{p})$, in which $\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}$ and $\mathbb{E}_{\mathrm{gn1}(\mathrm{gp1})}$, defined in Eq. (5), play a very important role.
(iii)As given in Eq. (30), at $T=0 K$, the physical MIT-condition for $E$, is that $\kappa\left(\mathrm{E}^{*}=0, r_{d(a)}\right)=0$, at $\mathrm{E}^{*} \equiv \mathrm{E}-$ $\mathbb{E}_{\text {gni(gpi) }}=0$, according to the critical photon energy $E=E_{C P E}=\mathbb{E}_{\text {gni(gpi) }}$, being similar to the physical MIT-condition for N , as that given in (i).
(iv) As showed in Tables 3a, 3b and 3c, our expressions for optical coefficients are found to be more accurate than the corresponding ones, being obtained from the physical model proposed by Forouhi and Bloomer [11].
(v) Finally, as showed in Tables 4 n and 4 p , the extrema values of real (imaginary) parts of the complex dielectric functions, $\varepsilon_{1(2)}\left(E, r_{d(a)}\right)$, given in any $d(a)$-Si systems, occur at the same photon energy $E$.

Keywords: Effects of the impurity-size and heavy doping; effective autocorrelation function for potential fluctuations; optical coefficients; critical photon energy

## 1. Introduction

In our two previous papers [1, 2, 3], referred here to as I, II and III.
In I and II, our new expression for the extrinsic static dielectric constant, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathrm{r}_{\mathrm{d}(\mathrm{a})}$ being the donor (acceptor) d(a)-radius, was determined by using an effective Bohr model, suggesting that, with an increasing $r_{d(a)}, \varepsilon\left(r_{d(a)}\right)$, due to such the impurity size effect, decreases, affecting strongly the critical impurity density in the metal-insulator transition, and also the optical coefficients, given in $n(p)$-type degenerate Si crystal, for the reduced Fermi energy [4], $\boldsymbol{\xi}_{\mathbf{n}(\mathbf{p})}(\geqq \mathbf{1})$. Therefore, all the numerical results of those obtained and given in III are now revised and performed, in comparison with those obtained in [5-12], as given in the following Sections 1-5.

## 2. Energy-band-structure parameters

First of all, we present in the following Table 1 the values of the energy-band-structure parameters, given in the $n(p)$-type Si-crystal, such as: (i) if denoting the free electron mass by $m_{0}$, the relative effective electron (hole) mass, $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}$, which is equal to the relative effective mass, $\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}$ [5], as used in this Sections 2 and 4 to determine the critical impurity density in the MIT, and (ii) to the reduced effective mas, $\mathrm{m}_{\mathrm{r}}=$ $\frac{m_{n} \times m_{p}}{m_{n}+m_{p}} \times m_{o}$, as used in Sections 3 and 5 to determine the optical band gap and the optical coefficients in the $\mathrm{n}(\mathrm{p})$-type degenerate Si . Further, $\mathbb{E}_{\mathrm{go}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}=\mathrm{r}_{\mathrm{Si}}\right)=1.17 \mathrm{eV}[4]$ is the unperturbed intrinsic band gap, as used in Section 3 to determine the optical band gap, $\varepsilon_{0}=11.4$ [6] is the relative intrinsic dielectric constant, the critical impurity density in the MIT, $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{P}(\mathrm{B})}\right)=3.52\left(4.06 \times 10^{18} \mathrm{~cm}^{-3}[3,7]\right.$, and finally, the effective averaged numbers of equivalent conduction (valence)-band edge, $g_{c(v)}=3(2)[4,7]$, used here.

Table 1. For increasing $r_{d(a)}$, while $\varepsilon\left(r_{d}\right)$ decreases, the functions: $\mathbb{E}_{\text {gni(gpi) }}\left(r_{d(a)}\right), N_{C D n(N D p)}\left(r_{d(a)}\right)$ and $N_{C D n(C D p)}^{E E T}\left(r_{d(a)}\right)$ increase. The relative deviations between the numerical results of $N_{C D n}\left(r_{d}\right)$ and $N_{C D n}^{E B T}\left(r_{d}\right)$, calculated using Equations (3,21), are verry small, of the order of $9.8 \times 10^{-6}$, suggesting that $N_{C D n(N D p)}\left(r_{d(a)}\right)$ can be well explained by $\mathrm{N}_{\mathrm{CDn}}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}}\right)$, being localized in the EBT.

We now determine our expression for extrinsic static dielectric constant, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, due to the impurity size effect, and the expression for critical density, $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, characteristic of the MIT, as follows.

### 2.1. Expression for $\boldsymbol{\varepsilon}\left(\mathbf{r}_{\mathbf{d}(\mathbf{a})}\right)$

In the [d(a)-semiconductors]-systems, since $r_{d(a)}$, given in tetrahedral covalent bonds, is usually either larger or smaller than $\mathrm{r}_{\mathrm{do}(\mathrm{ao})} \equiv \mathrm{r}_{\mathrm{Si}}$, a local mechanical strain (or deformation potential energy) is induced, according to a compression (dilation) for: $\mathrm{r}_{\mathrm{d}(\mathrm{a})}>\mathrm{r}_{\mathrm{do}(\mathrm{ao})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}<\mathrm{r}_{\mathrm{do}(\mathrm{ao})}\right)$, due to the $\mathrm{d}(\mathrm{a})$-size effect, respectively [1]. Then, we have shown that this $r_{d(a)}$-effect affects the changes in all the energy-bandstructure parameters, expressed in terms of the static dielectric constant, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, determined as follows.

At $T=0 \mathrm{~K}$, we shown [1, 2] that, as $\mathrm{r}_{\mathrm{d}(\mathrm{a})}>\mathrm{r}_{\mathrm{do}(\mathrm{ao})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}<\mathrm{r}_{\mathrm{do}(\mathrm{ao})}\right)$, such the compression (dilatation) corresponding the repulsive (attractive) force increases (decreases) the intrinsic energy gap $\mathbb{E}_{\text {gni }(g \mathrm{gi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ and the effective donor(acceptor)-ionization energy $\mathbb{E}_{\mathrm{d}(\mathrm{a})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ in absolute values, obtained in an effective Bohr model, as [1]:
$\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)-\mathbb{E}_{\mathrm{go}}\left(\mathrm{r}_{\mathrm{Si}}\right)=\mathbb{E}_{\mathrm{d}(\mathrm{a})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)-\mathbb{E}_{\mathrm{do}(\mathrm{ao})}\left(\mathrm{r}_{\mathrm{Si}}\right)=\mathbb{E}_{\mathrm{do}(\mathrm{ao})}\left(\mathrm{r}_{\mathrm{Si}}\right) \times\left[\left(\frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)}\right)^{2}-1\right]$,
where $\mathbb{E}_{\mathrm{do}(\mathrm{ao})}\left(\mathrm{r}_{\mathrm{Si}}\right) \equiv \frac{13600 \mathrm{meV} \times\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}\right)}{\varepsilon_{o}^{2}}$ and

One notes that $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ decreases with an increasing $\mathrm{r}_{\mathrm{d}(\mathrm{a})}$.

### 2.2. Our expressions for the critical density in the MIT

In the $\mathrm{n}(\mathrm{p})$-type degenerate Si-crystals, the critical donor(acceptor)-density, $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, is determined from the generalized effective Mott criterion in the MIT, as:
$\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)^{1 / 3} \times \mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\mathrm{z}, \mathrm{z}=0.290364495(0.3687017088)$,
and the effective Bohr radius $\mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is given by:
$\mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \frac{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a}}\right) \times \hbar^{2}}{\left(\mathrm{~m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{0}\right) \times \mathrm{q}^{2}}=0.53 \times 10^{-8} \mathrm{~cm} \times \frac{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)}{\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{0}\right)}$,
where -q is the electron charge, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is determined in Eq. (2), and $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}=$ $0.3216(0.3664)$. It should be noted in Eq. (3) that, for the Mott criterion in the MIT, $\mathrm{z}_{\text {Mott }}=0.25$, while in the present work, $\mathrm{z}=0.290364495$ ( 0.3687017088 ), is chosen so that we can obtain the exact values of $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{P}(\mathrm{B})}\right)=3.52(4.06) \times 10^{18} \mathrm{~cm}^{-3}$ [3, 7], as those given in Table 1. Further, these obtained results can also be justified by those of the densities of electrons (holes) localized in exponential conduction (valance)-band (EBT) tails, $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDP})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{P}(\mathrm{B})}\right) \equiv \mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{P}(\mathrm{B})}\right)=3.52(4.06) \times 10^{18} \mathrm{~cm}^{-3}$, obtained using Eq. (21), as investigated in Section 4, and reported also in Table 1. In this Table, we also present various values of $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, and $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, noting that the maximal relative deviations, in absolute values, $|R D|$, between $N_{C D n(N D p)}\left(r_{d(a)}\right)$ and $N_{C D n(C D p)}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{Ba})}\right)$ are found to be equal to: $9.8(0.49) \times 10^{-6}$, respectively. In other word, $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, determined in Eq. (3), can be explained by the densities of electrons (holes) localized in exponential conduction (valance)-band (EBT) tails, $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, determined in Eq. (21). Furthermore, in our recent work [7], we showed that, in the $n(p)$-type degenerate Si , the critical densities of electrons (holes) can also be determined from the spin-susceptibility singularities (SSS), obtained at $N=N_{C D n(C D p)}^{S S S}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, at which the MITs occur.
Table 1 also indicates that, for increasing $\mathrm{r}_{\mathrm{d}(\mathrm{a})}, \varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ decreases, while $\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ and $N_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ increase, affecting strongly all the physical properties, as those given in following Sections 3-5.

## 3. Optical band gap

Here, $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}$ is chosen as: $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{r}} / \mathrm{m}_{\mathrm{o}}=0.1713$, and then, if denoting $\mathrm{N}^{*} \equiv \mathrm{~N}-$ $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, the optical band gap (OBG) is found to be given by:
$\mathbb{E}_{\mathrm{gn1} 1(\mathrm{gp} 1)}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right) \equiv \mathbb{E}_{\mathrm{gn2} 2(\mathrm{gp} 2)}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right)+\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{~T}\right)$,
where the Fermi energy $\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{~T}\right)$ is determined in Eq. (A3) of the Appendix A and the reduced band gap is defined by:
$\mathbb{E}_{\mathrm{gn2} 2(\mathrm{gp} 2)}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right) \equiv \mathbb{E}_{\mathrm{gnei}(\mathrm{gpei})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}, T\right)-\Delta \mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$.
Here, the effective intrinsic band gap $\mathbb{E}_{\text {gnei(gpei) }}$ is determined by:
$\mathbb{E}_{\text {gnei(gpei) }}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}, T\right) \equiv \mathbb{E}_{\text {gni(gpi) }}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)-0.071 \mathrm{eV} \times\left\{\left(1+\left[\frac{2 \mathrm{~T}}{440.6913}\right]^{2.201}\right)^{\frac{1}{2.201}}-1\right\}$,
and the band gap narrowing, $\Delta \mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, are determined in Equations (B3, B4) of the Appendix B and the intrinsic energy gap $\mathbb{E}_{\text {gni (gpi) }}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is defined in in Eq. (1).
Then, as noted in the Appendix A and B , at $\mathrm{T}=0 \mathrm{~K}$, as $\mathrm{N}^{*}=0$, one has: $\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{~T}\right)=\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}\right)=$ 0 , as given in Eq. (A4), and $\Delta \mathbb{E}_{\text {gni }(g \mathrm{gi)}}^{*}\left(\mathrm{~N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, T\right)=0$, or $\Delta \mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, according to the MIT, as noted in Appendix A and B. Therefore, $\mathbb{E}_{\text {gn1 } 1(\mathrm{gp} 1)}=\mathbb{E}_{\mathrm{gn2} 2(\mathrm{gp} 2)}=\mathbb{E}_{\text {gnei }(\mathrm{gpei})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\mathbb{E}_{\text {gni }(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ at $\mathrm{T}=0 \mathrm{~K}$ and $\mathrm{N}^{*}=0$, according also to the MIT.
Finally, the numerical results of $\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp} 1)}\left(\mathrm{N}^{*}>0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right)$ at $\mathrm{T}=20 \mathrm{~K}$, calculated using Eq. (5), expressed as functions of N and $\mathrm{r}_{\mathrm{d}(\mathrm{a})}$, and reported in Table 3 of I , being also compared with the corresponding data [8], obtained in the $\mathrm{P}(\mathrm{B})$-type degenerate Si , giving rise to the accuracies of the order of $1.16 \%$ $(2.68 \%)$, respectively. Here, we also showed that, in the $\mathrm{n}(\mathrm{p})$-type degenerate Si and for a given photon energy $\mathrm{E} \equiv \hbar \omega$, since the extinction coefficient, $\kappa_{n(p)}$, and other optical coefficients, as discussed in III, are expressed in terms of the function $\left(E-\mathbb{E}_{\mathrm{gn1}(\mathrm{gp} 1)}\right)^{2}$. Therefore, if the values of $\mathbb{E}_{\mathrm{gn1} 1(\mathrm{gp} 1)}$ obtained in Table 3 of III, increase (decrease), $\left(E-\mathbb{E}_{\mathrm{gn}}\right)^{2}$ and other optical coefficients then decrease (increase), respectively, as showed in Figures 3a, 3b and 3c of our previous paper II.

## 4. Physical model and mathematical methods

### 4.1. Physical model

In the $n(p)$-type degenerate Si , if denoting the Fermi wave number by: $\mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}(\mathrm{N}) \equiv\left(3 \pi^{2} \mathrm{~N} / \mathrm{g}_{\mathrm{c}(\mathrm{v})}\right)^{1 / 3}$, the effective reduced Wigner-Seitz radius $\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}$, characteristic of the interactions, is defined by
$\gamma \times \mathrm{r}_{\mathrm{sn}(\mathrm{sp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*}\right) \equiv \frac{\mathrm{k}_{\mathrm{Pr}(\mathrm{Fp})}^{-1}}{a_{\mathrm{Bn}(\mathrm{Pp})}}<1$,
being proportional to $\mathrm{N}^{*-1 / 3}$. Here, $\gamma=(4 / 9 \pi)^{1 / 3}, \mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}^{-1}$ means the averaged distance between ionized donors (acceptors), and $\mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is determined in Eq. (4).
Then, the ratio of the inverse effective screening length $\mathrm{k}_{\mathrm{sn}(\mathrm{sp})}$ to Fermi wave number $\mathrm{k}_{\mathrm{Fn}(\mathrm{kp})}$ at 0 K is defined by
$\mathrm{R}_{\mathrm{sn}(\mathrm{sp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \frac{\mathrm{k}_{\mathrm{sn}(\mathrm{sp})}}{\mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}}=\frac{\mathrm{k}_{\mathrm{pr}(\mathrm{Fp})}^{-1}}{\mathrm{k}_{\mathrm{sn}(\mathrm{sp})}^{-1}}=\mathrm{R}_{\mathrm{snWS}(\mathrm{spWS})}+\left[\mathrm{R}_{\mathrm{snTF}(\mathrm{spTF})}-\mathrm{R}_{\mathrm{snWS}(\mathrm{spWS})}\right] e^{-\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}}<1$.
These ratios, $\mathrm{R}_{\text {snTF(spTF) }}$ and $\mathrm{R}_{\text {snWS(spWS) }}$, can be determined as follows.

First, for $N \gg \mathrm{~N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, according to the Thomas-Fermi (TF)-approximation, the ratio $\mathrm{R}_{\mathrm{snTF}(\mathrm{snTF})}$ is reduced to
$\mathrm{R}_{\mathrm{snTF}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \frac{\mathrm{k}_{\mathrm{snTF}(\mathrm{spTF})}}{\mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}}=\frac{\mathrm{k}_{\mathrm{Fr}(\mathrm{Fp})}^{-1}}{\mathrm{k}_{\mathrm{snTF}(\mathrm{sp} T \mathrm{~F})}^{-1}}=\sqrt{\frac{4 \gamma \mathrm{r}_{\mathrm{sn}(\mathrm{sp})}}{\pi}} \ll 1$,
being proportional to $\mathrm{N}^{-1 / 6}$.
Secondly, $N<\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, according to the Wigner-Seitz (WS)-approximation, the ratio $\mathrm{R}_{\mathrm{snWS}(\mathrm{snWS})}$ is reduced to
$\mathrm{R}_{\mathrm{sn}(\mathrm{sp}) \mathrm{WS}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \frac{\mathrm{k}_{\mathrm{sn}(\mathrm{sp}) \mathrm{WS}}}{\mathrm{k}_{\mathrm{Fn}}}=\left(\frac{3}{2 \pi}-\gamma \frac{\mathrm{d}\left[r_{\operatorname{sn}(\mathrm{sp})}^{2} \times \mathbb{E}_{\mathrm{CE}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)\right]}{\mathrm{d} r_{\mathrm{sn}}(\mathrm{sp})}\right)$,
where $\mathbb{E}_{C E}\left(\mathrm{~N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is the majority-carrier correlation energy (CE), being determined in Eq. (B2) of the Appendix B.

Furthermore, as given in II, in the highly degenerate case, the physical conditions are found to be given by :
$\frac{\mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}^{-1}}{\mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}}<\frac{\eta_{\mathrm{n}(\mathrm{p})}}{\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}} \equiv \frac{1}{\mathrm{~A}_{\mathrm{n}(\mathrm{p})}}<\frac{\mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}^{-1}}{\mathrm{k}_{\mathrm{sn}(\mathrm{sp})}^{-1}} \equiv \mathrm{R}_{\mathrm{sn}(\mathrm{sp})}<1, \mathrm{~A}_{\mathrm{n}(\mathrm{p})} \equiv \frac{\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}}{\eta_{\mathrm{n}(\mathrm{p})}}$,
being needed to determine the expression for electrical conductivity, as investigated in Section 5. Here, $R_{s n(s p)}$ is determined in Eq. (7).

Then, in degenerate $d(a)$-Si systems, the total screened Coulomb impurity potential energy due to the attractive interaction between an electron(hole) charge, $-q(+q)$, at position $\overrightarrow{\mathrm{r}}$, and an ionized donor (ionized acceptor) charge: $+q(-q)$ at position $\overrightarrow{\mathrm{R}_{\mathrm{j}}}$, randomly distributed throughout the Si crystal, is defined by
$V(r) \equiv \sum_{j=1}^{\mathbb{N}} \mathrm{V}_{\mathrm{j}}(\mathrm{r})+\mathrm{V}_{\mathrm{o}}$,
where $\mathbb{N}$ is the total number of ionized donors(acceptors), $V_{o}$ is a constant potential energy, and $v_{j}(r)$ is a screened Coulomb potential energy for each d(a)-Si system, defined as
$\mathrm{v}_{\mathrm{j}}(\mathrm{r}) \equiv-\frac{\mathrm{q}^{2} \times \exp \left(-\mathrm{k}_{\mathrm{snn}(\mathrm{sp})} \times \overrightarrow{\mathrm{r}}-\overrightarrow{\mathrm{R}}_{\mathrm{j}} \mid\right)}{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \times\left|\overrightarrow{\mathrm{r}}-\overrightarrow{\mathrm{R}_{\mathrm{j}}}\right|}$,
where $\mathrm{k}_{\mathrm{sn}(\mathrm{sp})}$ is the inverse screening length determined in Eq. (7).
Further, using a Fourier transform, the $v_{j}$-representation in wave vector $\vec{k}$-espace is given by
$\mathrm{v}_{\mathrm{j}}(\overrightarrow{\mathrm{k}})=-\frac{\mathrm{q}^{2}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)} \times \frac{4 \pi}{\Omega} \times \frac{1}{\mathrm{k}^{2}+\mathrm{k}_{\mathrm{sn}}^{2}}$,
where $\Omega$ is the total Si-crystal volume.
Then, the effective auto-correlation function for potential fluctuations, $W_{n(p)}\left(v_{n(p)}, N^{*}, r_{d}\right) \equiv\left\langle V(r) V\left(r^{\prime}\right)\right\rangle$, was determined in II, as :
$\mathrm{W}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \eta_{\mathrm{n}(\mathrm{p})}^{2} \times \exp \left(\frac{-\mathcal{H} \times \mathrm{R}_{\mathrm{snn}(\mathrm{p})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)}{2 \sqrt{\left|v_{\mathrm{n}(\mathrm{p})}\right|}}\right), \eta_{\mathrm{n}(\mathrm{p})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \frac{\sqrt{2 \pi \mathrm{~N}^{*}}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)} \times \mathrm{q}^{2} \mathrm{k}_{\mathrm{sn}(\mathrm{sp})}^{-1 / 2}, v_{\mathrm{n}(\mathrm{p})} \equiv \frac{-\mathbb{E}}{\mathbb{E}_{\mathbb{E}_{\mathrm{nn}(\mathrm{Fpo})}}}$.
Here, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is determined in Eq. (2), $\mathrm{R}_{\mathrm{sn}(\mathrm{sp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ in Eq. (7), the empirical Heisenberg parameter $\mathcal{H}=$ 3.320313702 will be chosen such that the determination of the density of electrons localized in the conduction(valence)-band tails, determined in Section 5 would be accurate, and finally $v_{\mathrm{n}(\mathrm{p})} \equiv \frac{-\mathbb{E}}{\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}}$,
where $\mathbb{E}$ is the total electron energy and $\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}$ is the Fermi energy at 0 K , determined in Eq. (A4) of the Appendix A.

In the following, we will calculate the ensemble average of the function: $(\mathbb{E}-V)^{\mathrm{a}-\frac{1}{2}} \equiv \mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}$, for $\mathrm{a} \geq 1$, $\mathbb{E}_{\mathrm{k}} \equiv \frac{\hbar^{2} \times \mathrm{k}^{2}}{2 \times m_{n(p)}^{*}}$ being the kinetic energy of the electron (hole), and $V(\mathrm{r})$ determined in Eq. (11), by using the two following integration methods, as developed in II, which strongly depend on $\mathrm{W}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$.

### 4.2. Mathematical methods and their application (Critical impurity density)

## A. Kane integration method (KIM)

In heavily doped d(a)-Si systems, the effective Gaussian distribution probability is defined by $\mathrm{P}(\mathrm{V}) \equiv \frac{1}{\sqrt{2 \pi W_{\mathrm{n}(\mathrm{P})}}} \times \exp \left[\frac{-\mathrm{V}^{2}}{2 W_{\mathrm{n}(\mathrm{P})}}\right]$.
So, in the Kane integration method, the Gaussian average of $(\mathbb{E}-V)^{a-\frac{1}{2}} \equiv \mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}$ is defined by $\left\langle(\mathbb{E}-V)^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\text {KIM }} \equiv\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}}=\int_{-\infty}^{\mathbb{E}}(\mathbb{E}-V)^{\mathrm{a}-\frac{1}{2}} \times P(V) \mathrm{dV}$, for $a \geq 1$.

Then, by variable changes: $s=(\mathbb{E}-V) / \sqrt{W_{n(p)}} \quad$ and $\quad x=-\mathbb{E} / \sqrt{W_{n(p)}} \equiv A_{n(p)} \times v_{n(p)} \times \exp \left(\frac{\mathcal{H} \times R_{\text {sn(sp) }}}{4 \times \sqrt{\left|\operatorname{lv}_{n(p)}\right|} \mid}\right)$, and using an identity:
$\int_{0}^{\infty} \mathrm{s}^{\mathrm{a}-\frac{1}{2}} \times \exp \left(-\mathrm{xs}-\frac{\mathrm{s}^{2}}{2}\right) \mathrm{ds} \equiv \Gamma\left(a+\frac{1}{2}\right) \times \exp \left(\mathrm{x}^{2} / 4\right) \times \mathrm{D}_{-\mathrm{a}-\frac{1}{2}}(\mathrm{x})$,
where $D_{-a-\frac{1}{2}}(x)$ is the parabolic cylinder function and $\Gamma\left(a+\frac{1}{2}\right)$ is the Gamma function, one thus has:
$\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\text {KIM }}=\frac{\exp \left(-\mathrm{x}^{2} / 4\right) \times \mathrm{W}_{\mathrm{n}(\mathrm{p})}^{\frac{2 \mathrm{a}}{4}}}{\sqrt{2 \pi}} \times \Gamma\left(\mathrm{a}+\frac{1}{2}\right) \times \mathrm{D}_{-\mathrm{a}-\frac{1}{2}}(\mathrm{x})=\frac{\exp \left(-\mathrm{x}^{2} / 4\right) \times \mathrm{n}_{\mathrm{n}(\mathrm{p})}^{\mathrm{a}-\frac{1}{2}}}{\sqrt{2 \pi}} \times \exp \left(-\frac{\mathcal{H} \times \mathrm{R}_{\operatorname{sn}(\mathrm{sp})} \times(2 \mathrm{a}-1)}{8 \times \sqrt{\left|\ln _{\mathrm{n}(\mathrm{p})}\right|}}\right) \times \Gamma(\mathrm{a}+$
$\left.\frac{1}{2}\right) \times D_{-a-\frac{1}{2}}(x)$.

## B. Feynman path-integral method (FPIM)

Here, the ensemble average of $(\mathbb{E}-V)^{\mathrm{a}-\frac{1}{2}} \equiv \mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}$ is defined by $\left\langle(\mathbb{E}-V)^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\text {FPIM }} \equiv\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\text {FPIM }} \equiv \frac{\hbar^{\mathrm{a}-\frac{1}{2}}}{2^{3 / 2} \times \sqrt{2 \pi}} \times \frac{\Gamma\left(\mathrm{a}+\frac{1}{2}\right)}{\Gamma\left(\frac{3}{2}\right)} \times \int_{-\infty}^{\infty}(i \mathrm{t})^{-\mathrm{a}-\frac{1}{2}} \times \exp \left\{\frac{i \mathbb{E t}}{\hbar}-\frac{\left(\mathrm{t} \sqrt{\left.W_{\mathrm{n}(\mathrm{p}}\right)^{2}}\right.}{2 \hbar^{2}}\right\} \mathrm{dt}, \mathrm{i}^{2}=-1$, noting that as $\mathrm{a}=1$, (it) $)^{-\frac{3}{2}} \times \exp \left\{-\frac{\left(\mathrm{t} \sqrt{W_{\mathrm{p}}}\right)^{2}}{2 \hbar^{2}}\right\}$ is found to be proportional to the averaged Feynman propagator given the dense donors(acceptors).
Then, by variable changes: $\mathrm{t}=\frac{\hbar}{\sqrt{\mathrm{W}_{\mathrm{n}(\mathrm{p})}}}$ and $\mathrm{x}=-\mathbb{E} / \sqrt{\mathrm{W}_{\mathrm{n}(\mathrm{p})}}$, and then using an identity:
$\int_{-\infty}^{\infty}(i s)^{-a-\frac{1}{2}} \times \exp \left\{i x s-\frac{s^{2}}{2}\right\} d s \equiv 2^{3 / 2} \times \Gamma(3 / 2) \times \exp \left(-x^{2} / 4\right) \times D_{-a-\frac{1}{2}}(x)$,
one finally obtains: $\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{FPIM}} \equiv\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}},\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}}$ being determined in Eq. (13).

In the following, with use of asymptotic forms for $D_{-a-\frac{1}{2}}(x)$, those given for $\left\langle(\mathbb{E}-V)^{a-\frac{1}{2}}\right\rangle_{\text {KIM }}$ will be obtained in the two cases: $\mathbb{E} \geq 0$ and $\mathbb{E} \leq 0$.

## (i) $\mathbb{E} \geq 0$-case

As $\mathbb{E} \rightarrow+\infty$, one has: $v_{\mathrm{n}} \rightarrow-\infty$ and $\mathrm{x} \rightarrow-\infty$. In this case, one gets:

$$
\mathrm{D}_{-\mathrm{a}-\frac{1}{2}}(\mathrm{x} \rightarrow-\infty) \approx \frac{\sqrt{2 \pi}}{\Gamma\left(\mathrm{a}+\frac{1}{2}\right)} \times e^{\frac{\mathrm{x}^{2}}{4}} \times(-\mathrm{x})^{\mathrm{a}-\frac{1}{2}}
$$

Therefore, Eq. (13) becomes: $\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}} \approx \mathbb{E}^{\mathrm{a}-\frac{1}{2}}$. Further, as $\mathbb{E} \rightarrow+0$, one has: $v_{\mathrm{n}(\mathrm{p})} \rightarrow-0$ and $\mathrm{x} \rightarrow-\infty$. So, one gets :
$D_{-a-\frac{1}{2}}(x \rightarrow-\infty) \simeq \beta(a) \times \exp \left(\left(\sqrt{a}+\frac{1}{16 a^{\frac{3}{2}}}\right) \mathrm{x}-\frac{\mathrm{x}^{2}}{16 \mathrm{a}}+\frac{\mathrm{x}^{3}}{24 \sqrt{\mathrm{a}}}\right) \rightarrow 0, \quad \beta(\mathrm{a})=\frac{\sqrt{\pi}}{2^{\left.\frac{2 a+1}{4} \Gamma\left(\frac{a}{2}+\frac{3}{4}\right)\right]} .}$
Thus, as $\mathbb{E} \rightarrow+0$, from Eq. (13), one gets: $\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}} \rightarrow 0$.
In summary, for $\underline{\mathbb{E}} \geq 0$, the expression of $\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}}$ can be approximated by:
$\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}} \cong \mathbb{E}^{\mathrm{a}-\frac{1}{2}}, \quad \mathbb{E}_{\mathrm{k}} \equiv \frac{\hbar^{2} \times \mathrm{k}^{2}}{2 \times \mathrm{m}^{*}}$.
(ii) $\mathbb{E} \leq 0$ - case.

As $\mathbb{E} \rightarrow-0$, from Eq. (13), one has: $v_{\mathrm{n}(\mathrm{p})} \rightarrow+0$ and $\mathrm{x} \rightarrow+\infty$. Thus, one first obtains, for any $\mathrm{a} \geq 1$,
$D_{-a-\frac{1}{2}}(x \rightarrow \infty) \simeq \beta(a) \times \exp \left[-\left(\sqrt{a}+\frac{1}{16 a^{2}}\right) x-\frac{x^{2}}{16 a}-\frac{x^{3}}{24 \sqrt{a}}\right] \rightarrow 0, \beta(a)=\frac{\sqrt{\pi}}{\left.2^{\frac{2 a+1}{4}} \Gamma\left(\frac{a}{2}+\frac{3}{4}\right)\right]}$, noting that
$\beta(1)=\frac{\sqrt{\pi}}{2^{\frac{3}{4}} \times \Gamma(5 / 4)}$ and $\beta(5 / 2)=\frac{\sqrt{\pi}}{2^{3 / 2}}$.
Then, putting $f(a) \equiv \frac{\eta^{a-\frac{1}{2}}}{\sqrt{\eta_{n(p)}}} \sqrt{2 \pi} \times \Gamma\left(a+\frac{1}{2}\right) \times \beta(a)$, Eq. (13) yields
$\mathrm{H}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})} \rightarrow+0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)=\frac{\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}} \mathrm{f}_{\text {KıM }}\right.}{\mathrm{f}(\mathrm{a})}=\exp \left[-\frac{\mathcal{H} \times \mathrm{R}_{\mathrm{sn}(\mathrm{sp})} \times(2 \mathrm{a}-1)}{8 \times \sqrt{\left|\mathrm{v}_{\mathrm{n}(\mathrm{p})}\right|}}-\left(\sqrt{\mathrm{a}}+\frac{1}{16 \mathrm{a}^{\frac{3}{2}}}\right) \mathrm{x}-\left(\frac{1}{4}+\frac{1}{16 \mathrm{a}}\right) \mathrm{x}^{2}-\frac{\mathrm{x}^{3}}{24 \sqrt{\mathrm{a}}}\right] \rightarrow 0$.
Further, as $\mathbb{E} \rightarrow-\infty$, one has: $v_{\mathrm{n}(\mathrm{p})} \rightarrow+\infty$ and $\mathrm{x} \rightarrow \infty$. Thus, one gets:
$D_{-a-\frac{1}{2}}(x \rightarrow \infty) \approx x^{-a-\frac{1}{2}} \times e^{-\frac{x^{2}}{4}} \rightarrow 0$. Therefore, Eq. (13) yields
$\mathrm{K}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})} \rightarrow+\infty, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right) \equiv \frac{\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}}}{\mathrm{f}(\mathrm{a})} \simeq \frac{1}{\beta(\mathrm{a})} \times \exp \left(-\frac{\left(\mathrm{A}_{\mathrm{n}(\mathrm{p})} \times v_{\mathrm{n}(\mathrm{p}))^{2}}^{2}\right.}{2}\right) \times\left(\mathrm{A}_{\mathrm{n}(\mathrm{p})} \times v_{\mathrm{n}(\mathrm{p})}\right)^{-\mathrm{a}-\frac{1}{2}} \rightarrow 0$.
It should be noted that, as $\mathbb{E} \leq 0$, the ratios (15) and (16) can be taken in an approximate form as:
$\mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)=\mathrm{K}_{\mathrm{n}(\mathrm{p})}\left(\nu_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)+\left[\mathrm{H}_{\mathrm{n}(\mathrm{p})}\left(\nu_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)-\mathrm{K}_{\mathrm{n}(\mathrm{p})}\left(\nu_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)\right] \times \exp \left[-\mathrm{c}_{1} \times\right.$
$\left.\left(A_{n(p)} v_{n(p)}\right)^{c_{2}}\right]$,
such that: $\mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right) \rightarrow \mathrm{H}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)$ for $0 \leq v_{\mathrm{n}} \leq 16 \quad$, and $\mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right) \rightarrow$ $\mathrm{K}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)$ for $v_{\mathrm{n}(\mathrm{p})} \geq 16$. Here, the constants $\mathrm{c}_{1}$ and $\mathrm{c}_{2}$ may be respectively chosen as: $\mathrm{c}_{1}=10^{-40}$
and $c_{2}=80$, as $\mathrm{a}=1$, being used to determine the critical density of electrons (holes) localized in the exponential conduction(valence) band-tails (EBT), $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{N}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, in the following.

## C. Critical impurity density in the MIT

In degenerate $\mathrm{d}(\mathrm{a})$-Si systems at $\mathrm{T}=0 \mathrm{~K}$, in which $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}=0.3216(0.3664)$, as given in Table 1, using Eq. (13), for $\mathrm{a}=1$, the density of states $\mathcal{D}(\mathbb{E})$ is defined by:
$\left\langle\mathcal{D}\left(\mathbb{E}_{\mathrm{k}}\right)\right\rangle_{\mathrm{KIM}} \equiv \frac{\mathrm{g}_{\mathrm{c}(v)}}{2 \pi^{2}}\left(\frac{2 \mathrm{~m}_{\mathrm{n}(\mathrm{p})}}{\hbar^{2}}\right)^{\frac{3}{2}} \times\left\langle\mathbb{E}_{\mathrm{K}}^{\frac{1}{2}}\right\rangle_{\mathrm{KIM}}=\frac{\mathrm{g}_{c(v)}}{2 \pi^{2}}\left(\frac{2 \mathrm{~m}_{\mathrm{n}(\mathrm{p})}}{\hbar^{2}}\right)^{\frac{3}{2}} \times \frac{\exp \left(-\frac{x^{2}}{4}\right) \times \mathrm{W}_{\mathrm{n}}^{\frac{1}{4}}}{\sqrt{2 \pi}} \times \Gamma\left(\frac{3}{2}\right) \times \mathrm{D}_{-\frac{3}{2}}(\mathrm{x})=\mathcal{D}(\mathbb{E})$,
where x is defined in Eq. (13), as: $\mathrm{x}=-\mathbb{E} / \sqrt{\mathrm{W}_{\mathrm{n}(\mathrm{p})}} \equiv \mathrm{A}_{\mathrm{n}(\mathrm{p})} \times v_{\mathrm{n}(\mathrm{p})} \times \exp \left(\frac{\mathcal{H} \times \mathrm{R}_{\mathrm{sn}(\mathrm{sp})}}{4 \times \sqrt{\left|\mathrm{v}_{\mathrm{n}(\mathrm{p})}\right|}}\right)$.
Here, $\mathbb{E}_{\text {Fno }}$ is determined in Eq. (A4) of the Appendix A, with $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}$ and $\mathcal{H}=$ 3.320313702 , being chosen such that the following determination of $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{N}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ would be accurate.

Going back to the functions: $H_{n}, K_{n}$ and $F_{n}$, given respectively in Equations (15-17), in which the factor $\frac{\left\langle\mathbb{E}_{k}^{\frac{1}{2}} \text { KIM }\right.}{\mathrm{f}(\mathrm{a}=1)}$ is now replaced by:
$\frac{\left\langle\mathbb{E}_{\mathrm{K}}^{\frac{1}{2}} \mathrm{KIM}\right.}{\mathrm{f}(\mathrm{a}=1)}=\frac{\mathcal{D}(\mathbb{E} \leq 0)}{\mathcal{D}_{0}}=\mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}=1\right), \mathcal{D}_{\mathrm{o}}=\frac{\mathrm{g}_{\mathrm{c}(\mathrm{y})} \times\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})} \times \mathrm{m}_{0}\right)^{3 / 2} \times \sqrt{\eta_{\mathrm{n}(\mathrm{p})}}}{2 \pi^{\pi^{3}}} \times \beta(\mathrm{a}=1), \beta(\mathrm{a}=1)=\frac{\sqrt{\pi}}{2^{\frac{3}{4} \times \Gamma(5 / 4)}}$.

Therefore, $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{N}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ can be defined by
$N_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{N}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\int_{-\infty}^{0} \mathcal{D}(\mathbb{E} \leq 0) \mathrm{dE}$,
where $\mathcal{D}(\mathbb{E} \leq 0)$ is determined in Eq. (19). Then, by a variable change: $v_{\mathrm{n}(\mathrm{p})} \equiv \frac{-\mathbb{E}}{\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}}$, one obtains:
$N_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{N}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\frac{\mathrm{g}_{\mathrm{c}(\mathrm{v})} \times\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})}\right)^{3 / 2} \sqrt{\eta_{\mathrm{n}(\mathrm{p})}} \times \mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}}{2 \pi^{2} \hbar^{3}} \times\left\{\int_{0}^{16} \beta(\mathrm{a}=1) \times \mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}=1\right) \mathrm{d} v_{\mathrm{n}(\mathrm{p})}+\mathrm{I}_{\mathrm{n}(\mathrm{p})}\right\}$,
where
$\mathrm{I}_{\mathrm{n}(\mathrm{p})} \equiv \int_{16}^{\infty} \beta(\mathrm{a}=1) \times \mathrm{K}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}=1\right) \mathrm{d} v_{\mathrm{n}(\mathrm{p})}=\int_{16}^{\infty} e^{\frac{\left.-\left(\mathrm{A}_{\mathrm{n}(\mathrm{p})}\right)^{2} v_{\mathrm{n}}\right)^{2}}{2}} \times\left(\mathrm{A}_{\mathrm{n}(\mathrm{p})} v_{\mathrm{n}(\mathrm{p})}\right)^{-3 / 2} \mathrm{~d} v_{\mathrm{n}(\mathrm{p})}$.
Here, $\beta(\mathrm{a}=1)=\frac{\sqrt{\pi}}{2^{\frac{3}{4} \times \Gamma(5 / 4)}}$.
Then, by another variable change: $\mathrm{t}=\left[\mathrm{A}_{\mathrm{n}(\mathrm{p})} v_{\mathrm{n}(\mathrm{p})} / \sqrt{2}\right]^{2}$, the integral $\mathrm{I}_{\mathrm{n}(\mathrm{p})}$ yields:
$I_{n(p)}=\frac{1}{2^{5 / 4} A_{n_{n}(p)}} \times \int_{y_{n(p)}}^{\infty} t^{b-1} e^{-t} d t \equiv \frac{\Gamma\left(b, y_{n}(p)\right)}{2^{5 / 4} \times A_{n}(p)}$,
where $\mathrm{b}=-1 / 4, \mathrm{y}_{\mathrm{n}(\mathrm{p})}=\left[16 \mathrm{~A}_{\mathrm{n}(\mathrm{p})} / \sqrt{2}\right]^{2}$, and $\Gamma\left(\mathrm{b}, \mathrm{y}_{\mathrm{n}(\mathrm{p})}\right)$ is the incomplete Gamma function, defined by:
$\Gamma\left(\mathrm{b}, \mathrm{y}_{\mathrm{n}(\mathrm{p})}\right) \simeq \mathrm{y}_{\mathrm{n}(\mathrm{p})}^{\mathrm{b}-1} \times e^{-\mathrm{y}_{\mathrm{n}(\mathrm{p})}}\left[1+\sum_{\mathrm{j}=1}^{16} \frac{(\mathrm{~b}-1)(\mathrm{b}-2) \ldots(\mathrm{b}-\mathrm{j})}{\mathrm{y}_{\mathrm{n}(\mathrm{p})}}\right]$.

Finally, Eq. (20) now yields:
$N_{\operatorname{CDn}(C D p)}^{\mathrm{EDT}}\left[\mathrm{N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right]=\frac{\mathrm{g}_{\mathrm{c}(\mathrm{y})} \times\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})}\right)^{3 / 2} \sqrt{\eta_{(\mathrm{p})} \times \mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}}}{2 \pi^{2} \hbar^{3}} \times\left\{\int_{0}^{16} \beta(\mathrm{a}=1) \times\right.$
$\left.\mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}=1\right) \mathrm{d} v_{\mathrm{n}(\mathrm{p})}+\frac{\Gamma\left(\mathrm{b}, y_{\mathrm{n}(\mathrm{p})}\right.}{2^{5 / 4} \times \mathrm{A}_{\mathrm{n}(\mathrm{p})}}\right\}$,
being the density of electrons(holes) localized in the exponential conduction(valence)-band tails (EBT), respectively.
The numerical results of $N_{\operatorname{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left[\mathrm{N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right] \equiv \mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, for a simplicity of presentation, evaluated using Eq. (21), are given in Table 2 of III, confirming thus those of $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, calculated using Eq. (3), with a precision of the order of $9.8(4.91) \times 10^{-6}$, respectively. In other word, this critical $\mathrm{d}(\mathrm{a})$-density $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a}))}\right)$ can thus be explained by the density of electrons(holes) localized in the EBT, $N_{\operatorname{CDn}(\operatorname{CDp})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, respectively.
So, the effective density of free electrons (holes), $\mathrm{N}^{*}$, given in the parabolic conduction (valence) band of the degenerate $\mathrm{d}(\mathrm{a})-\mathrm{Si}$ systems, can thus be expressed by:
$\mathrm{N}^{*} \equiv \mathrm{~N}-\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})} \cong \mathrm{N}-\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}$.
Then, if $\mathrm{N}^{*}=\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}$, according to the Fermi energy, $\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}=\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\right) \equiv \frac{\hbar^{2} \times \mathrm{K}_{\mathrm{Fn}(\mathrm{Fp})}^{2}\left(\mathrm{~N}^{*}\right)}{2 \times \mathrm{m}_{\mathrm{n}(\mathrm{P})}}$, then the value of the density of electrons(holes), $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}$, localized in the EBT for $\mathbb{E} \leq 0$, is almost equal to $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}$, given in this parabolic conduction (valence) band, for $\mathbb{E} \geq 0$. This can be expressed as:
$\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}} \cong \mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}$, as $\mathrm{N}^{*} \equiv \mathrm{~N}_{\mathrm{CDn}(\mathrm{NDp})}$.

## 5. Optical coefficients

Optical properties of any medium can be described by the complex refraction index $\mathbb{N}$ and the complex dielectric function $\varepsilon, \mathbb{N} \equiv \mathrm{n}-\mathrm{i} \kappa$ and $\varepsilon \equiv \varepsilon_{1}-\mathrm{i} \varepsilon_{2}$, where $\mathrm{i}^{2}=-1$ and $\varepsilon \equiv \mathbb{N}^{2}$. Therefore, the real and imaginary parts of $\varepsilon$ denoted by $\varepsilon_{1}$ and $\varepsilon_{2}$ can thus be expressed in terms of the refraction index n and the extinction coefficient $\kappa$ as: $\varepsilon_{1} \equiv \mathrm{n}^{2}-\kappa^{2}$ and $\varepsilon_{2} \equiv 2 \mathrm{n} \kappa$. One notes that the optical absorption coefficient $\alpha$ is related to $\varepsilon_{2}, \mathrm{n}, \kappa$, and the optical conductivity $\sigma_{0}$ by [3]

where the effective photon energy: $\mathbb{E}^{*}=\mathrm{E}-\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}=\mathbb{E}$ is the reduced photon energy, the band gap $\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}$ can be equal to the optical band gap $\mathbb{E}_{\text {gn1 } 1(g p 1)}$ and intrinsic band gap $\mathbb{E}_{\text {gni(gpi) }}$, determined in Eq. (5). Here, $\mathrm{E} \equiv \hbar \omega,-\mathrm{q}, \hbar,|\mathrm{v}(\mathrm{E})|, \omega, \varepsilon_{\text {free space }}, \mathrm{c}$ and $\mathrm{J}\left(\mathrm{E}^{*}\right)$ respectively represent: the photon energy, electron charge, Dirac's constant, matrix elements of the velocity operator between valence (conduction)-and-conduction (valence) bands in $n(p)$-type semiconductors, photon frequency, permittivity of free space, velocity of light, and joint density of states. It should be noted that, if the three functions such as: $|\mathrm{v}(\mathrm{E})|^{2}, \mathrm{~J}\left(\mathrm{E}^{*}\right)$ and $\mathrm{n}(\mathrm{E})$ are
known, then the other optical dispersion functions given in Eq. (24) can thus be determined. Moreover, the normal-incidence reflectance, $R(E)$, can be expressed in terms of $\kappa(E)$ and $n(E)$ as:
$R(E)=\frac{[n(E)-1]^{2}+\kappa(E)^{2}}{[n(E)+1]^{2}+\kappa(E)^{2}}$.
From Equations $(24,25)$, if the two optical functions, $\varepsilon_{1}$ and $\varepsilon_{2}$, (or n and $\kappa$ ), are both known, the other ones defined above can thus be determined.

Then, using a transformation for the joint density of states, given in allowed indirect Si-transitions, for $a=5 / 2$, as discussed in II, one has:
$\mathrm{J}_{\mathrm{n}(\mathrm{p})}\left(\mathrm{E} \geq \mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\right)=\frac{1}{2 \pi^{2}} \times\left(\frac{2 \mathrm{~m}_{\mathrm{r}}}{\hbar^{2}}\right)^{3 / 2} \times \frac{\left(\mathrm{E}-\mathrm{E}_{\mathrm{gn}(\mathrm{gp})}\right)^{\mathrm{a}-(1 / 2)}}{E_{\text {gni(gpi) }}^{a-1}}=\frac{1}{2 \pi^{2}} \times\left(\frac{2 \mathrm{~m}_{\mathrm{r}}}{\hbar^{2}}\right)^{3 / 2} \times \frac{\left(\mathrm{E}-\mathbb{E}_{\mathrm{gn}(\mathrm{gp}))^{2}}\right.}{E_{\text {gni(gpi) }}^{3 / 2}}$, for $\mathrm{a}=5 / 2$.
Therefore, from Equations $(24,26)$, for $E \geq \mathbb{E}_{g n(g p)}$, or for $E^{*}=E-\mathbb{E}_{g n(g p)}=\mathbb{E} \geq 0$, the extinction coefficient $\kappa$ can be determined by:
$\kappa\left(\mathrm{E} \geq \mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\right)=\mathrm{f}(\mathrm{E}) \times\left(\mathrm{E}^{*}=\mathrm{E}-\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\right)^{2}, \mathrm{f}(\mathrm{E})=\frac{\mathrm{q}^{2} \times \mathrm{m}_{\mathrm{r}}^{3 / 2} \times|\mathrm{v}(\mathrm{E})|^{2}}{\sqrt{2} \times \pi^{2} \times \varepsilon_{0} \times \hbar \times \mathrm{n}(\mathrm{E}) \times \mathrm{E}^{2} \times E_{\text {gni (gpi) }}^{3 / 2}}$,
noting that the optical function such as: $n(E)$ and $\kappa\left(E \geq \mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\right)$, were parameterized by various authors [10-12]. First of all, one notes that, as $E \rightarrow \infty$, Forouhi and Bloomer (FB) [11] claimed model that $\kappa(E \rightarrow$ $\infty) \rightarrow$ a constant, while Jellison and Modine [12] and Van Cong [3] showed that their proposed expressions quickly go to 0 as $E^{-3}$, and consequently, the optical functions such as: $\sigma_{0}(E)$ and $\alpha(E)$, given in Eq. (24), both go 0 as $E^{-2}$.
In the following, we will propose: $\kappa(E \rightarrow \infty) \rightarrow 0$ as $E^{-1}$ so that $\sigma_{0}(E \rightarrow \infty)$ and $\alpha(E \rightarrow \infty)$ both go to their appropriate limiting constants.
Then, if defining the band gap $\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}$, equal to the optical band gap $\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp} 1)}$ or to the intrinsic band gap $\mathbb{E}_{\text {gni(gpi) }}$, and taking into account the above remarks, we now propose:
$\kappa\left(E^{*} \geq 0\right)=f(E) \times\left(E^{*} \equiv E-\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\right)^{2}, \mathrm{f}(\mathrm{E})=\sum_{\mathrm{i}=1}^{4} \frac{\mathrm{~A}_{\mathrm{i}}}{E^{2} \times\left(1+10^{-4} \times \frac{E}{6}\right)-\mathrm{B}_{\mathrm{i}} E+\mathrm{C}_{\mathrm{i}}}$,
being equal to 0 for $E^{*}=0$ (or for $E=\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}$ ) and also going to 0 as $E^{-1}$ as $E \rightarrow \infty$, and then,
$n(E)=n_{\infty}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)+\sum_{\mathrm{i}=1}^{4} \frac{\mathrm{~B}_{\mathrm{oi}} E+\mathrm{C}_{\mathrm{oi}}}{E^{2}-\mathrm{B}_{\mathrm{i}} E+\mathrm{C}_{\mathrm{i}}}$,
going to a constant as $E \rightarrow \infty$, since $n\left(E \rightarrow \infty, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=n_{\infty}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\sqrt{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)} \times \frac{\omega_{T}}{\omega_{L}}, \omega_{T}=9.9 \times 10^{13} \mathrm{~s}^{-1}$ [5] and $\omega_{L}=16.8464 \times 10^{13} s^{-1}$, according to $n_{\infty}\left(\mathrm{r}_{\mathrm{P}}\right)=2$, being obtained from the Lyddane-Sachs-Teller relation [5], from which $T(L)$ represents the transverse (longitudinal) optical phonon mode.
Here, other parameters are determined by: $B_{o i}=\frac{A_{i}}{Q_{i}} \times\left[-\frac{B_{i}^{2}}{2}+E_{\text {gnei }(\text { gpei })} B_{i}-E_{\text {gnei(gpei) }}^{2}+C_{i}\right], C_{o i}=\frac{A_{i}}{Q_{i}} \times$ $\left[\frac{\mathrm{B}_{\mathrm{i}} \times\left(E_{\text {gnei }}^{2} \text { (gpei) }+\mathrm{C}_{\mathrm{i}}\right)}{2}-2 \mathbb{E}_{\text {gnei(gpei) }} \mathrm{C}_{\mathrm{i}}\right], \quad \mathrm{Q}_{\mathrm{i}}=\frac{\sqrt{4 \mathrm{C}_{\mathrm{i}}-\mathrm{B}_{\mathrm{i}}^{2}}}{2}, \quad$ where, $\quad$ for $\quad \mathrm{i}=(1, \quad 2, \quad 3, \quad$ and 4$), \quad A_{i}=$ 0.004374, $0.0154,0.0738$ and $0.1889 \quad, \quad B_{i}=6.885,7.401,8.634$ and 10.652 , and $C_{i}=$ $11.864,13.754,18.812$, and 29.841 .

The important numerical results of the above optical functions, at $\mathrm{T}=0 \mathrm{~K}, \mathrm{~N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}$, and for $E=\mathbb{E}_{\text {gni(gi) }}$, are reported in following Tables $2 \mathrm{a}, 2 \mathrm{~b}$ and 2 c , and Tables $3 \mathrm{a}, 3 \mathrm{~b}$ and 3 c , in which they are also discussed, and compared with the corresponding ones, calculated and obtained from FB-model [11], and also with the corresponding data given by Aspnes and Studna [9].

Table 2a. At the MIT, $\mathrm{T}=0 \mathrm{~K}, \mathrm{~N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{p})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, and the critical photon energy $E_{C P E}=\mathrm{E}=\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \kappa_{M I T}\left(\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=$ $0, \varepsilon_{2(M I T)}\left(\mathbb{E}_{\text {gni }(g \mathrm{i})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0, \sigma_{O(M I T)}\left(\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$ and $\alpha_{M I T}\left(\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, and the other functions such as : $\mathrm{n}_{\text {MIT }}\left(\mathbb{E}_{\text {gni }(\mathrm{gpi})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \varepsilon_{1(M I T)}\left(\mathbb{E}_{\text {gni }(\mathrm{gpi})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, and $R_{M I T}\left(\mathbb{E}_{\text {gni }(\mathrm{gpi})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ decrease with increasing $\mathrm{r}_{\mathrm{d}(\mathrm{a})}$ and $\mathbb{E}_{\text {gni }}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$.

Table 2c. Here, the choice of the real refraction index: $n\left(E \rightarrow \infty, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=n_{\infty}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\sqrt{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)} \times \frac{\omega_{T}}{\omega_{L}}, \omega_{T}=9.9 \times 10^{13} \mathrm{~s}^{-1}$ [5] and $\omega_{L}=16.8464 \times 10^{13} s^{-1}$, obtained from the Lyddane-Sachs-Teller relation [5], from which $T(L)$ represents the transverse (longitudinal) optical phonon mode, giving rise to $n_{\infty}\left(\mathrm{r}_{\mathrm{P}}\right)=2$, and further, that of the asymptotic behavior, given for the extinction coefficient: $\kappa_{\infty}\left(E \rightarrow \infty, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \rightarrow 0$, as $E^{-1}$, so that $\sigma_{0}\left(E \rightarrow \infty, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ and $\alpha\left(E \rightarrow \infty, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ both go to their appropriate limiting constants, are found to be very important, affecting strongly the numerical results of the other optical coefficients.

Table 3a. In the P-Si system, at $T=0 K$, our numerical results of the following optical coefficients, expressed as functions of E , and calculated using Equations $(24,25,28,29)$, for $\mathbb{E}_{g n}\left(r_{P}\right)=\mathbb{E}_{g n i}\left(r_{P}\right)[=1.1689 \mathrm{eV}]$, and the corresponding ones, obtained from the FB-model [11], are reported in the following Table 2a, in which the relative deviations (RDs) of those are also given and calculated, for $1.5 \leq E(\mathrm{eV}) \leq 6$, using the Aspnes-and-Studna (AS)-data [9]. Here, as noted in above Table 2c, one obtains: $\kappa_{\infty}\left(E \rightarrow \infty, \mathrm{r}_{P}\right) \rightarrow$ 0 and $\varepsilon_{2, \infty}\left(E \rightarrow \infty, \mathrm{r}_{\mathrm{P}}\right) \rightarrow 0$, while, in the FB-model, $\kappa_{\infty(F B)}\left(E \rightarrow \infty, \mathrm{r}_{\mathrm{P}}\right)=0.2615$ and $\varepsilon_{2, \infty(F B)}\left(E \rightarrow \infty, \mathrm{r}_{\mathrm{P}}\right)=1.0196$.

Table 3b. In the P-Si system, at $T=0 \mathrm{~K}$, our numerical results of the following optical coefficients, expressed as functions of E , and calculated using Equations $(24,25,28,29)$, for $\mathbb{E}_{g n}\left(r_{P}\right)=\mathbb{E}_{g n i}\left(r_{P}\right)[=1.1689 \mathrm{eV}]$, and the corresponding ones, obtained from the FB-model [11], are reported in the following Table 2a, in which the relative deviations (RDs) of those are also given and calculated, for $1.5 \leq E(\mathrm{eV}) \leq 6$, using the Aspnes-and-Studna (AS)-data [9]. Here, as noted in above Table 2c, one obtains: $\alpha_{\infty}\left(E \rightarrow \infty, \mathrm{r}_{\mathrm{p}}\right)=$ $1.7122 \times 10^{9} \mathrm{~cm}^{-1}$ and $\sigma_{0, \infty}\left(E \rightarrow \infty, \mathrm{r}_{\mathrm{P}}\right)=7.2548 \times 10^{5}\left(\frac{1}{\Omega \times c m}\right)$, while, in the FB-model, $\propto_{F B} \rightarrow \infty$, and $\sigma_{O(F B)} \rightarrow \infty$, which should be not correct.

| E in eV | $\propto\left(10^{3} \times \mathrm{cm}^{-1}\right) ; \mathrm{RD} \%$ | R; RD\% | $\sigma_{O}\left(\frac{1}{\Omega \times c m}\right)$ | $\sigma_{O(F B)}\left(\frac{1}{\Omega \times c m}\right)$ | $\propto_{F B}\left(10^{3} \times \mathrm{cm}^{-1}\right) ; \mathrm{RD} \%$ | $R_{F B} ; \mathrm{RD} \%$ |

Some important cases, given in various physical conditions, are considered as follows.

### 5.1. Metal-insulator transition (MIT)-case

As discussed in Equations (21-23) and Eq. (A4) of the Appendix A, the physical conditions used for the MIT are: $\quad \mathrm{T}=0 \mathrm{~K}, \quad \mathrm{~N}^{*}=0 \quad$ or $\quad \mathrm{N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})} \cong \mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}$, vanishing the Fermi energy: $\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}\right) \equiv \frac{\hbar^{2} \times \mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}^{2}\left(\mathrm{~N}^{*}\right)}{2 \times \mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*}}=0$. Further, from the discussions given Eq. (5) for the optical band gap: $\mathbb{E}_{\operatorname{gn} 1(\mathrm{gp} 1)}\left(\mathrm{N}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}=0\right)=\mathbb{E}_{\text {gnei }(\text { gpei }}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\mathbb{E}_{\text {gni }(\text { gpi })}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, according also to the MIT.
Then, in this MIT-case, replacing both $\mathbb{E}_{\text {gnei(gpei) }}$ and $\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp} 1)}$, by $\mathbb{E}_{\text {gni(gpi) }}$, given in Equations $(28,29)$, and consequently from Eq. (24), one gets, for the effective photon energy $E^{*} \equiv E-\mathbb{E}_{\text {gni(gpi) }}=0$ :
$\kappa\left(\mathrm{E}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0, \varepsilon_{2}\left(\mathrm{E}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0, \sigma_{0}\left(\mathrm{E}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$ and $\alpha\left(\mathrm{E}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, corresponding also to the MIT. Thus, in this case, the photon energy E becomes the critical photon energy, defined by:
$E_{\text {CPE }}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \mathbb{E}_{\text {gni(gpi) }}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$. Therefore, Equations $(28,29)$, obtained in the MIT-case, become:
$\kappa\left(E^{*}=0\right)=f\left(E_{\mathrm{gni}(\mathrm{gpi})}\right) \times\left(E^{*} \equiv E_{\mathrm{CPE}}-\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}=0\right)^{2}=0$,
$n\left(E=\mathbb{E}_{\text {gni }(\mathrm{gpi})}\right)=n_{\infty}+\sum_{\mathrm{i}=1}^{4} \frac{\mathrm{~B}_{\mathrm{o}} E+\mathrm{C}_{\mathrm{oi}}}{E^{2}-\mathrm{B}_{\mathrm{i}} E+\mathrm{C}_{\mathrm{i}}}$, in which $\mathbb{E}_{\text {gnei }(\mathrm{gpei})}=\mathbb{E}_{\text {gni }(\mathrm{gpi})}$.
Then, going back to the remark given in Eq. (23), we can determine the values of some optical coefficients for $\mathbb{E} \leq 0$, representing the exponential tail-states, which can be deduced from Eq. (30), by putting: $E^{*}=$ $\mathbb{E}_{\text {gni }(\text { gpi })}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, as:
$\kappa^{E E C-T}\left(\mathbb{E}_{\text {gni }}(\mathrm{gpi})\right)=f\left(\mathbb{E}_{\text {gni }(\mathrm{gpi})}\right) \times \mathbb{E}_{\text {gni }(\text { gpi })}^{2}$.
Now, replacing Equations $(31,32)$ into Equations $(24,25)$, one obtains for $\mathbb{E} \leq 0$ the expressions, obtained for the following exponential tail-states of $\varepsilon_{2}, \sigma_{0}(E), \alpha$, and $R$ as:
$\varepsilon_{2}^{E I m D C-T}\left(\mathbb{E}_{\text {gni }(\mathrm{gpi})}\right)=2 \times \kappa^{E E C-T}\left(\mathbb{E}_{\text {gni }(\mathrm{gpi})}\right) \times n\left(E=\mathbb{E}_{\text {gni }(\mathrm{gpi})}\right)$,
$\sigma_{O}^{E O C-T}\left(\mathbb{E}_{\text {gni }(\mathrm{gpi})}\right)=\frac{\varepsilon_{\text {free space }} \times \mathbb{E}_{\text {gni }}(\text { gpi })}{} \times \varepsilon_{2}^{E I m D-T}\left(\mathbb{E}_{\text {gni }}(\mathrm{gpi})\right)$,
$\alpha^{E O A C-T}\left(\mathbb{E}_{\text {gni(gpi) }}\right)=\frac{2 \times \mathbb{E}_{\text {gni(gpi) }} \times \kappa^{E E C-T}\left(\mathbb{E}_{\text {gni(gpi) }}\right)}{\hbar \times c}$, and
$\left.\mathrm{R}^{N I R-T}\left(\mathbb{E}_{\text {gni }(\text { gpi })}\right)=\frac{\left[\mathrm{n}\left(\mathbb{E}_{\text {gni }}(\mathrm{gii})-1\right]^{2}+\kappa^{E E C-T}\left(\mathbb{E}_{\text {gni }}(\mathrm{gpi})\right)^{2}\right.}{\left[\mathrm{n}\left(\mathbb{E}_{\text {gni }}(\mathrm{gii})+1\right]^{2}+\kappa^{E E C-T}\left(\mathbb{E}_{\text {gni }}(\text { gpi })\right.\right.}\right)^{2}$.
The numerical results of those optical functions, determined by Equations (31-36, 24), were discussed and reported in the above Table 2 b .

### 5.2. Extrema values of $\boldsymbol{\varepsilon}_{1(2)}$ as functions of photon energy $E$

From Equations $(24,28,29)$, we can determine the extrema values of typical optical functions $\varepsilon_{1(2)}\left(E, r_{d(a)}\right)$ in following physical conditions by: $\mathrm{T}=0 \mathrm{~K}$ and $\mathrm{N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{NDP})}$, and by: $\mathrm{T}=20 \mathrm{~K}$ and $N=1.5(1.7) \times$ $10^{20} \mathrm{~cm}^{-3}$, respectively, as given in following Tables 4 n and 4 p , in which the arrows ( $\uparrow \downarrow$ ) indicates the maximum, and $(\downarrow \uparrow)$ the minimum and the extrema-values of those occur at the same corresponding photon energy E .
Table 4n. In d-Si systems, and for two types of physical conditions such as: $\left(T=0 K\right.$ and $N=N_{C D n}\left(r_{d}\right)$ ) and ( $T=20 K, N=$ $1.5 \times 10^{20} \mathrm{~cm}^{-3}$ ), the extrema values of $\varepsilon_{1}(E)$ and $\varepsilon_{2}(E)$, calculated using Equations $(24,28,29)$, vary with increasing E ,
represented by the arrows: $\uparrow$ or $\downarrow$, suggesting that their extrema occur at the same E.

### 5.3. Variations of various optical coefficients as functions of $N$, typically for some d(a)-Si systems

Also, from Equations $(24,28,29)$, we can determine the variations of various optical coefficients at 20 K , as functions of N , typically for $\mathrm{E}=3.34 \mathrm{eV}$ and for some $(\mathrm{P}, \mathrm{Te}, \mathrm{Sn})$-Si systems and ( $\mathrm{B}, \mathrm{Ga}, \mathrm{In}$ )-Si ones, being indicated by the arrows: $\nearrow$ and $\searrow$, as tabulated in following Tables 5 n and 5 p , in which the physical condition $\mathrm{N}>\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\right.$ or $\left.\mathrm{N}^{*}>0\right)$ must be respected, and their variations thus depend on the ones of the optical band gap, $\mathbb{E}_{\operatorname{gn} 1(g p 1)}\left(N^{*}, r_{d(a)}\right)$.

Table 5n. In ( $\mathrm{P}, \mathrm{Te}, \mathrm{Sn}$ )-Si systems, our numerical results of the following optical coefficients, expressed as functions of N , and calculated using Equations ( $31-36,24$ ), for $\mathrm{E}=3.34 \mathrm{eV}$ and $\mathrm{T}=20 \mathrm{~K}$, present the variations by arrows, ( $\downarrow$ and $\nearrow$ ), since those of the optical gap $\mathbb{E}_{\mathrm{gn} 1}\left(\mathrm{~N}^{*}, \mathrm{r}_{\mathrm{d}}\right)$, are presented by $(\nearrow$ and $\searrow)$ or by $(\downarrow$ and $\nearrow)$.

## 5．4．Variations of various optical coefficients as functions of T，typically for some d（a）－Si systems

Here，from Equations（24，28，29），we can determine the variations of various optical coefficients at $N=$ $1.5(3) \times 10^{19} \mathrm{~cm}^{-3}$ ，respectively，as functions of T ，typically for $\mathrm{E}=3.34 \mathrm{eV}$ and for some $(\mathrm{P}, \mathrm{Te}, \mathrm{Sn})-\mathrm{Si}$ systems and（B，Ga，In）－Si ones，being indicated by the arrows：$\nearrow$ and $\downarrow$ ，as given in following Tables 6 n and 6 p ，in which their variations thus depend on the ones of the reduced Fermi energy，$\xi_{\mathrm{n}(\mathrm{p})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}, T\right)$ ．

Table 6n．In（P，Te，Sn）－Si systems，our numerical results of the following optical coefficients，expressed as functions of T，and calculated using Equations（31－36，24），for $\mathrm{E}=3.34 \mathrm{eV}$ and $\mathrm{N}=1.5 \times 10^{19} \mathrm{~cm}^{-3}$ ，increase with increasing $T$ ，since the optical band gap $\mathbb{E}_{\mathrm{gn} 1}\left(\mathrm{~T}, \mathrm{r}_{\mathrm{d}}\right)$ decreases with increasing T ．

## 6. Concluding remarks

In the $\mathrm{n}(\mathrm{p})$-type degenerate Si-crystal, by using the same physical model, as that given in Eq. (7), and same mathematical methods, as those proposed in I, II and III, and further, by taking into account the corrected values of energy-band-structure parameters, and mainly the correct asymptotic behaviors of the refraction index n and extinction coefficient $\kappa$, as the photon energy $E(\rightarrow \infty)$, all the numerical results, obtained in III, are now revised and performed.
So, by basing on our following basic expressions, as:
(i)the effective static dielectric constant, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, due to the impurity size effect, determined by an effective Bohr model [1], and given in Eq. (2),
(ii) the critical donor(acceptor)-density, $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, determined from the generalized effective Mott criterion in the MIT, and as given in Eq. (3), being used to determine the effective d(a)-density: $\mathrm{N}^{*} \equiv \mathrm{~N}-$ $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, which gives a physical condition, needed to define the metal-insulator transition (MIT) at $\mathrm{T}=0 \mathrm{~K}$, as: $\mathrm{N}^{*} \equiv \mathrm{~N}-\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}=0$ or $\mathrm{N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}$, noting that $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}$ can also be explained as the density of electrons(holes) localized in the exponential conduction(valence)-band tails (EBT), $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDP})}^{\mathrm{EBT}}$, as that determined in Eq. (21), with a precision of the order of $10^{-5}$, being observed in Table 1,
(iii) the Fermi energy, $\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{~T}\right)$, determined in Eq. (A3) of the Appendix A, with a precision of the order of $2.11 \times 10^{-4}$ [3], and finally,
(iv) the refraction index n and the extinction coefficient $\kappa$, determined in Equations (28, 29), verifying their correct asymptotic behaviors,
we have investigated the optical coefficients, determined from Equations (24, 25, 28, 29), and their numerical results, given in different physical conditions, have been obtained and discussed in above Tables $2 \mathrm{a}, 2 \mathrm{~b}, 2 \mathrm{c}, 3 \mathrm{a}, 3 \mathrm{~b}, 3 \mathrm{c}, 4 \mathrm{n}(4 \mathrm{p}), 5 \mathrm{n}(5 \mathrm{p})$, and finally $6 \mathrm{n}(6 \mathrm{p})$. In particular, in Tables $3 \mathrm{a}, 3 \mathrm{~b}$ and 3 c , our numerical
results for those optical coefficients are found to be more accurate than the corresponding ones, calculated from the physical model, proposed by Forouhi and Bloomer (FB) [11].
Finally, one notes that the MIT occurs in the degenerate case, in which:
(a) $\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}=0, \mathrm{~T}=0\right)=0$, determined by Eq. (A4) of the Appendix A, since it is proportional to $\left(\mathrm{N}^{*}\right)^{2 / 3}$,
(b) as discussed in Eq. (5), in the MIT, in which $\mathbb{E}_{\mathrm{gn1} 1(\mathrm{gp} 1)}\left(\mathrm{N}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}=0\right)=\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, where $\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp} 1)}$ and $\mathbb{E}_{\text {gni }(\mathrm{Fgpi})}$ are the optical band gap and intrinsic band gap, respectively, and c) as discussed in Section 5.1, as $E=E_{\text {CPE }}\left(r_{d(a)}\right) \equiv \mathbb{E}_{\text {gni }(g \mathrm{gi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ or the effective photon energy $\mathrm{E}^{*} \equiv$ $E-\mathbb{E}_{\text {gni }(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, one has: $\kappa\left(\mathrm{E}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0, \varepsilon_{2}\left(\mathrm{E}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0, \sigma_{0}\left(\mathrm{E}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$ and $\alpha\left(\mathrm{E}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, since those optical coefficients expressed in terms of $\left(\mathrm{E}^{*} \equiv \mathrm{E}-\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}=0\right)^{2}$, according also to the MIT-case, being new results.
In summary, all the numerical results, given in III [3], are now revised and performed in the present work.

## Appendix

## Appendix A. Fermi Energy and generalized Einstein relation

A1. In the $n(p)$-type Si-crystals, the Fermi energy $\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})} \equiv\left[\mathbb{E}_{\mathrm{fn}}-\mathbb{E}_{\mathrm{c}}\right]\left(\mathbb{E}_{\mathrm{Fp}} \equiv\left[\mathbb{E}_{\mathrm{v}}-\mathbb{E}_{\mathrm{fp}}\right]\right)$, $\mathbb{E}_{\mathrm{c}(\mathrm{v})}$ being the conduction (valence) band edges, obtained for any T and donor (acceptor) density N , being investigated in our previous paper, with a precision of the order of $2.11 \times 10^{-4}$ [3], is now summarized in the following. In this work, N is replaced by the effective density $\mathrm{N}^{*}, \mathrm{~N}^{*} \equiv \mathrm{~N}-\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ being the critical density, characteristic of the insulator-metal transition phenomenon. It means that $N^{*}=0$ at this transition.
First of all, we define the reduced electron density by:
$\mathrm{u}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right) \equiv \mathrm{u}\left(\mathrm{N}^{*}, \mathrm{~T}\right) \equiv \frac{\mathrm{N}^{*}}{\mathrm{~N}_{\mathrm{c}(\mathrm{v})}}, \mathrm{N}_{\mathrm{c}(\mathrm{v})}(\mathrm{T})=2 \times \mathrm{g}_{\mathrm{c}(\mathrm{v})} \times\left(\frac{\mathrm{m}_{\mathrm{n}(\mathrm{p})} \times \mathrm{k}_{\mathrm{B}} \mathrm{T}}{2 \pi h^{\frac{3}{2}}}\right)^{\frac{3}{2}}\left(\mathrm{~cm}^{-3}\right)$,
where $\mathrm{N}_{\mathrm{c}(\mathrm{v})}(T)$ is the conduction (valence)-band density of states, and the values of $\mathrm{g}_{\mathrm{c}(\mathrm{v})}$ and $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*}$ are defined and given in Table 1. Then, the reduced Fermi energy in the $n(p)$-type Si is determined by :
$\frac{\mathbb{E}_{\mathrm{F}_{n}}(\mathrm{u})}{\mathrm{K}_{\mathrm{B}} \mathrm{T}}\left(\frac{\mathbb{E}_{\mathrm{Fp}}(\mathrm{u})}{\mathrm{k}_{\mathrm{B}} \mathrm{T}}\right)=\frac{\mathrm{G}(\mathrm{u})+\mathrm{Au}^{\mathrm{B}} \mathrm{F}(\mathrm{u})}{1+\mathrm{Au}^{\mathrm{B}}}=\theta_{\mathrm{n}}(\mathrm{u}) \equiv \frac{\mathrm{V}(\mathrm{u})}{\mathrm{W}(\mathrm{u})}, \mathrm{A}=0.0005372$ and $\mathrm{B}=4.82842262$,
where $\mathrm{F}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right)=\mathrm{au}^{\frac{2}{3}}\left(1+\mathrm{bu}^{-\frac{4}{3}}+\mathrm{cu}^{-\frac{8}{3}}\right)^{-\frac{2}{3}}$, obtained for $\mathrm{u} \gg 1$, according to the degenerate cas, $\mathrm{a}=[(3 \sqrt{\pi} / 4)]^{2 / 3}, \quad \mathrm{~b}=\frac{1}{8}\left(\frac{\pi}{\mathrm{a}}\right)^{2}, \mathrm{c}=\frac{62.3739855}{1920}\left(\frac{\pi}{a}\right)^{4}$, and then $\mathrm{G}(\mathrm{u}) \simeq \operatorname{Ln}(\mathrm{u})+2^{-\frac{3}{2}} \times \mathrm{u} \times \mathrm{e}^{-\mathrm{du}}$ for $\mathrm{u} \ll$ 1 , according to the non - degenerate case, with: $d=2^{3 / 2}\left[\frac{1}{\sqrt{27}}-\frac{3}{16}\right]>0$.
So, in the present degenerate case ( $u \gg 1$ ), one has:
$\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right) \equiv \mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{~T}\right)=\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}(\mathrm{u}) \times\left(1+\mathrm{bu}^{-\frac{4}{3}}+\mathrm{cu}^{-\frac{8}{3}}\right)^{-\frac{2}{3}}$.

Then, at $T=0 K$, since $u^{-1}=0$, Eq. (A. 3 ) is reduced to:
$\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}\right) \equiv \frac{\hbar^{2} \times \mathrm{K}_{\mathrm{Rn}(\mathrm{Fp)}}^{2}\left(\mathrm{~N}^{*}\right)}{2 \times \mathrm{m}_{\mathrm{n}(\mathrm{P})}}$,
being proportional to $\left(\mathrm{N}^{*}\right)^{2 / 3}$, and equal to $0, \mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}=0\right)=0$, according to the MIT, as discussed in Section 2 and 3.

## Appendix B. Approximate forms for band gap narrowing (BGN)

First of all, in the $n(p)$-type Si-crystals, we define the effective reduced Wigner-Seitz radius $\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}$, characteristic of the interactions, by:
$\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv\left(\frac{3 \mathrm{~g}_{\mathrm{c}(\mathrm{v})}}{4 \pi \mathrm{~N}^{*}}\right)^{1 / 3} \times \frac{1}{\mathrm{a}_{\mathrm{Bn}(\mathrm{Bp)})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)}=1.1723 \times 10^{8} \times\left(\frac{\mathrm{g}_{\mathrm{c}(\mathrm{v})}}{\mathrm{N}^{*}}\right)^{1 / 3} \times \frac{\mathrm{m}_{\mathrm{n}(\mathrm{p}}^{*} / \mathrm{m}_{0}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)}$.
Here, the values of $\mathrm{g}_{\mathrm{c}(\mathrm{v})}=3(2)$ and $\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}\right)$ are defined and given in Table 1.
In particular, in the following, $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{r}} / \mathrm{m}_{\mathrm{o}}=0.1713$, is taken for evaluating the band gap narrowing (BGN), as used in Section 3. Therefore, the correlation energy of an effective electron gas, $\mathbb{E}_{\mathrm{CE}}\left(\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}\right)$, is found to be given by [1]:
$\mathbb{E}_{\mathrm{CE}}\left(\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}\right) \equiv \mathbb{E}_{\mathrm{CE}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\frac{-0.87553}{0.0908+\mathrm{r}_{\text {sn }(\mathrm{sp})}}+\frac{\frac{0.8753}{0.0908+\mathrm{r}_{\text {sn( }(\mathrm{sp})}}+\left(\frac{2[1-\ln (2)]}{\mathrm{n}^{2}}\right) \times \ln \left(\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}\right)-0.093288}{1+0.03847728 \times \mathrm{r}_{\mathrm{sn}(\mathrm{sp})}^{1.673876}}$.
Then, the band gap narrowing (BGN) can be determined by [1]:
$\Delta \mathbb{E}_{\mathrm{gn}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}}\right) \simeq \mathrm{a}_{1} \times \frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}}\right)} \times \mathrm{N}_{\mathrm{r}}^{1 / 3}+\mathrm{a}_{2} \times \frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}}\right)} \times \mathrm{N}_{\mathrm{r}}^{\frac{1}{3}} \times\left(2.503 \times\left[-\mathbb{E}_{\mathrm{CE}}\left(\mathrm{r}_{\mathrm{sn}}\right) \times \mathrm{r}_{\mathrm{sn}}\right]\right)+\mathrm{a}_{3} \times\left[\frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}}\right)}\right]^{5 / 4} \times$
$\sqrt{\frac{m_{\mathrm{v}}}{\mathrm{m}_{\mathrm{r}}}} \times \mathrm{N}_{\mathrm{r}}^{1 / 4}+\mathrm{a}_{4} \times \sqrt{\frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}}\right)}} \times \mathrm{N}_{\mathrm{r}}^{1 / 2} \times 2+\mathrm{a}_{5} \times\left[\frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}}\right)}\right]^{\frac{3}{2}} \times \mathrm{N}_{\mathrm{r}}^{\frac{1}{6}}, \mathrm{~N}_{\mathrm{r}} \equiv \frac{\mathrm{N}^{*}=\mathrm{N}-\mathrm{N}_{\mathrm{cD}}\left(\mathrm{r}_{\mathrm{d}}\right)}{9.999 \times 10^{17} c m^{-3}}$,
where $\quad a_{1}=6.829 \times 10^{-3}(\mathrm{eV}), a_{2}=1.168 \times 10^{-3}(\mathrm{eV}), a_{3}=5.032 \times 10^{-3}(\mathrm{eV}), a_{4}=10.058 \times$ $10^{-3}(\mathrm{eV})$ and $\mathrm{a}_{5}=1.455 \times 10^{-3}(\mathrm{eV})$, and
$\Delta \mathbb{E}_{\mathrm{gp}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{a}}\right) \simeq \mathrm{a}_{1} \times \frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{ra}_{\mathrm{a}}\right)} \times \mathrm{N}_{\mathrm{r}}^{1 / 3}+\mathrm{a}_{2} \times \frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{r}_{\mathrm{a}}\right)} \times N_{\mathrm{r}}^{\frac{1}{3}} \times\left(2.503 \times\left[-\mathbb{E}_{\mathrm{CE}}\left(\mathrm{r}_{\mathrm{sp}}\right) \times \mathrm{r}_{\mathrm{sp}}\right]\right)+\mathrm{a}_{3} \times\left[\frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{r}_{\mathrm{a}}\right.}\right]^{5 / 4} \times \sqrt{\frac{m_{\mathrm{c}}}{m_{\mathrm{r}}}} \times$
$\mathrm{N}_{\mathrm{r}}^{1 / 4}+2 \mathrm{a}_{4} \times \sqrt{\frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{ra}_{\mathrm{a}}\right)}} \times \mathrm{N}_{\mathrm{r}}^{1 / 2}+\mathrm{a}_{5} \times\left[\frac{\varepsilon_{0}}{\varepsilon\left(\mathrm{r}_{\mathrm{a}}\right)}\right]^{\frac{3}{2}} \times \mathrm{N}_{\mathrm{r}}^{\frac{1}{6}}, \mathrm{~N}_{\mathrm{r}} \equiv\left(\frac{\mathrm{N}^{*}=\mathrm{N}-\mathrm{N}_{\mathrm{cDp}}\left(\mathrm{r}_{\mathrm{a}}\right)}{9.999 \times 10^{17} \mathrm{~cm}^{-3}}\right)$,
where $\quad a_{1}=9.329 \times 10^{-3}(\mathrm{eV}), a_{2}=1.596 \times 10^{-3}(\mathrm{eV}), a_{3}=7.144 \times 10^{-3}(\mathrm{eV}), \quad a_{4}=13.741 \times$ $10^{-3}(\mathrm{eV})$ and $\mathrm{a}_{5}=1.988 \times 10^{-3}(\mathrm{eV})$.
Therefore, in Equations (B3, B4), as $T=0$ and $N^{*}=0$, and for any $r_{d(a)}, \Delta \mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\left(\mathrm{N}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, according to the MIT.
