# Accurate expressions for optical coefficients, given in n(p)-type heavily doped InSb-crystals, due to the impurity-size effect, and obtained from an improved Forouhi-Bloomer parameterization model (FB-PM) 

H. Van Cong<br>Université de Perpignan Via Domitia, Laboratoire de Mathématiques et Physique (LAMPS), EA 4217, Département de Physique, 52, Avenue Paul Alduy, F-66 860 Perpignan, France.<br>van-cong.huynh@univ-perp.fr ; huynhvc@outlook.fr

#### Abstract

In the $\mathrm{n}(\mathrm{p})$-type heavily doped InSb -crystals, at the temperature T and high $\mathrm{d}(\mathrm{a})$-density N , our expression for the static dielectric constant, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, expressed as a function of the donor (acceptor) radius, $\mathrm{r}_{\mathrm{d}(\mathrm{a})}$, and determined by using an effective Bohr model, as that investigated in [1,2], suggests that, for an increasing $\mathrm{r}_{\mathrm{d}(\mathrm{a})}$, due to such the impurity size effect, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ decreases, affecting strongly the critical $\mathrm{d}(\mathrm{a})$-density in the metal-insulator transition (MIT), $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, determined by Eq. (3), and its values are reported in Table 1, and also our accurate expressions for optical coefficients, obtained in Equations (24, 25, 28, 29), and their numerical results are given in Tables 2-6. Furthermore, one notes that, as observed in Table 3c, our obtained results of those optical coefficients are found to be more accurate than the corresponding ones, obtained from the FB-PM [11], suggesting thus that our present model, used here to study the optical properties of the $\mathrm{n}(\mathrm{p})$-type heavily doped InSb -crystals, is a good improved FB-PM, as observed in Table 3c.

Keywords: Effects of the impurity-size and heavy doping; effective autocorrelation function for potential fluctuations; optical coefficients; critical photon energy

## 1. Introduction

Our new expression for the extrinsic static dielectric constant, $\varepsilon\left(r_{d(a)}\right), r_{d(a)}$ being the donor (acceptor) $d(a)$ radius, was determined by using an effective Bohr model, suggesting that, with an increasing $\mathrm{r}_{\mathrm{d}(\mathrm{a})}$, due thus to such the impurity size effect, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ decreases, affecting strongly: the critical impurity density in the metal-insulator transition [1], and also optical properties, defined in heavily doped semiconductors [2, 3]. In the following Sections 2-5 [4, 11], in the n(p)-type heavily doped InSb-crystals, our numerical results of the optical coefficients, due to such the impurity-size effect, and obtained from an improved ForouhiBloomer parameterization model (IFB-PM), are presented, and also compared with the corresponding experimental-and-theoretical ones $[9,11]$, suggesting that our present model is found to be a good IFB-PM, as that observed in Table 3c. Finally, some concluding remarks are discussed and reported in Section 6.

## 2. Energy-band-structure parameters

First of all, in the following Table 1, we present the values of the energy-band-structure parameters, given in the $n(p)$-type InSb -crystal, such as: (i) if denoting the free electron mass by $\mathrm{m}_{\mathrm{o}}$, the effective electron (hole) mass, $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}$, which is respectively equal to the relative effective mass, $\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}=0.015$ (0.39) [5], as used in this Sections 2 and 4 to determine the critical impurity density in the metal-insulator transition (MIT), and (ii) to the reduced effective mas, $m_{r} / m_{o}=\frac{m_{n} \times m_{p}}{m_{n}+m_{p}}=0.014444$, as used in Sections 3 and 5 to determine the optical band gap and the optical coefficients given in the $\mathrm{n}(\mathrm{p})$-type heavily doped InSb crystals. Further, $\mathbb{E}_{\mathrm{go}}=\mathbb{E}_{\mathrm{gInSb}}=\mathbb{E}_{\mathrm{gSb}}=\mathbb{E}_{\mathrm{gIn}}=0.23 \mathrm{eV}$ [2] is the unperturbed intrinsic band gap, $\varepsilon_{\mathrm{InSb}}=\varepsilon_{\mathrm{In}}=$ $\varepsilon_{\mathrm{Sb}}=16.8$ is the relative static intrinsic dielectric constant of the InSb-crystal, and finally, the effective averaged numbers of equivalent conduction (valence)-band edge, $g_{c(v)}=1(1)$.
Table 1. For increasing $r_{d(a)}$, while $\varepsilon\left(r_{d}\right)$ decreases, the functions: $\mathbb{E}_{\text {gni }(g p i)}\left(r_{d(a)}\right), N_{C D n(N D p)}\left(r_{d(a)}\right)$ and $N_{C D n(C D p)}^{E B T}\left(r_{d(a)}\right)$ increase. The relative deviations between the numerical results of $N_{C D n}\left(r_{d}\right)$ and $N_{C D n}^{E B T}\left(r_{d}\right)$, calculated using Equations (3, 21), are found to be $11 \%$, suggesting that $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ can be explained by $\mathrm{N}_{\mathrm{CDn}}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}}\right)$, being localized in the EBT. So, in the $\mathrm{n}(\mathrm{p})$-type InSb , in which $\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}\right)=0.015(0.39)$ [4], all the numerical results for the energy-band-structure parameters and $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, expressed as functions of $\mathrm{r}_{\mathrm{d}(\mathrm{a})}$-radius, are obtained respectively, by using Equations $(3,9,10,11,12$, $13,21)$, suggesting that, with an increasing $r_{d(a)}, \varepsilon\left(r_{d(a)}\right)$ decreases, while $E_{d(a)}\left(r_{d(a)}\right), E_{\text {gni }\left(g p_{i}\right)}\left(r_{d(a)}\right)$ and $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)\left(\right.$ or $\left.\mathrm{N}_{\mathrm{CDn}}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}}\right)\right)$ increase, respectively.

We now determine our expression for extrinsic static dielectric constant, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, due to the impurity size effect, and the expression for critical density, $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, characteristic of the metal-insulator transition (MIT), as follows.

### 2.1. Expression for $\boldsymbol{\varepsilon}\left(\mathbf{r}_{\mathbf{d}(\mathbf{a})}\right)$

In the [d(a)-InSb]-systems, since $r_{d(a)}$, given in tetrahedral covalent bonds, is usually either larger or smaller than $\mathrm{r}_{\mathrm{sb}(\mathrm{In})}=0.136 \mathrm{~nm}(0.144 \mathrm{~nm})$, a local mechanical strain (or deformation potential energy) is induced, according to a compression (dilation) for: $\mathrm{r}_{\mathrm{d}(\mathrm{a})}>\mathrm{r}_{\mathrm{Sb}(\mathrm{In})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}<\mathrm{r}_{\mathrm{Sb}(\mathrm{In})}\right)$, due to the $\mathrm{d}(\mathrm{a})$-size effect, respectively $[1,2]$. Then, we have shown that this $r_{d(a)}$-effect affects the changes in all the energy-bandstructure parameters, expressed in terms of the static dielectric constant, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, determined as follows. At $\mathrm{T}=0 \mathrm{~K}$, we have showed $[1,2]$ that such the compression (dilatation) corresponds to the repulsive (attractive) force increases (decreases) the intrinsic energy gap $\mathbb{E}_{\text {gni }}\left(\underline{g i)}\left(r_{d(a)}\right)\right.$ and the effective donor(acceptor)-ionization energy $\mathbb{E}_{\mathrm{d}(\mathrm{a})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ in absolute values, obtained in an effective Bohr model, as:

where $\mathbb{E}_{\mathrm{do}(\mathrm{ao})} \equiv \frac{13600 \mathrm{meV} \times\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}\right)}{\varepsilon_{\mathrm{Sb}(\mathrm{n})}^{2}}=0.7227891 \mathrm{meV}(18.793 \mathrm{meV})$, and

$\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\frac{\varepsilon_{\mathrm{Ge}}}{\sqrt{1-\left[\left(\frac{\mathrm{r}_{\mathrm{d}(\mathrm{a})}}{S b(n)}\right)^{3}-1\right] \times \ln \left(\frac{\left.\mathrm{r}_{\mathrm{d}(\mathrm{a}}\right)^{3}}{s b(n n)}\right)^{3}}} \geq \varepsilon_{0},\left[\left(\frac{\mathrm{r}_{\mathrm{d}(\mathrm{a})}}{S b(I n)}\right)^{3}-1\right] \times \ln \left(\frac{\mathrm{r}_{\mathrm{d}(\mathrm{a})}}{S b(I n)}\right)^{3}<1$, for $\mathrm{r}_{\mathrm{d}(\mathrm{a})} \leq \mathrm{r}_{\mathrm{Sb}(\mathrm{In})}$.
In particular, in the $\mathrm{B}-\mathrm{InSb}$ system, in which $\frac{\mathrm{r}_{\mathrm{B}}=0.088 \mathrm{~nm}}{\mathrm{r}_{\mathrm{In}}=0.144 \mathrm{~nm}}=0.61 \ll 1$ this condition is not satisfied, since $\left[\left(\frac{r_{\mathrm{B}}}{\mathrm{r}_{\mathrm{I}}}\right)^{3}-1\right] \times \ln \left(\frac{\mathrm{r}_{\mathrm{B}}}{\mathrm{r}_{\mathrm{In}}}\right)^{3}=1.140245>1$. Therefore, as observed in Table 1, this B-InSb system was absent.

### 2.2. Our expressions for the critical density in the MIT

In the $n(p)$-type degenerate InSb-crystals, the critical donor(acceptor)-density, $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, is determined from the generalized effective Mott criterion in the MIT, as:
$\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)^{1 / 3} \times \mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=3.4714$ (0.133515),
and the effective Bohr radius $\mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is given by:
$\mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \frac{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a}}\right) \times \hbar^{2}}{\mathrm{~m}_{\mathrm{n}(\mathrm{p})} \times \mathrm{q}^{2}}=0.53 \times 10^{-8} \mathrm{~cm} \times \frac{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)}{\left.\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})}\right) / \mathrm{m}_{\mathrm{o}}\right)}$,
where -q is the electron charge, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is determined in Eq. (2), in which $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}=$ 0.015 (0.39). From Eq. (3), the numerical results of $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ are obtained and given in the above Table 1, in which we also report those of the densities of electrons (holes), being localized in exponential conduction (valance)-band (EBT) tails, $N_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, obtained using the next Eq. (21), as investigated in Section 4, noting that the maximal relative deviations (RD), in absolute values, between $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDP})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ and $N_{C D n(C D p)}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{Ba)}}\right)$ are found to be equal to: $7.8 \%$ (11\%), respectively. Thus, $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ determined in Eq. (3), can be explained by the densities of electrons (holes) localized in exponential conduction (valance)-band (EBT) tails, $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, determined from Eq. (21).
In summary, Table 1 also indicates that, for an increasing $r_{d(a)}, \varepsilon\left(r_{d(a)}\right)$ decreases, while $\mathbb{E}_{\text {gni }}\left(\right.$ gpi) $\left(r_{d(a)}\right)$, $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ and $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ increase, affecting strongly all the physical properties, as those observed in following Sections 3-5 .

## 3. Optical band gap

Here, $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}$ is chosen as: $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{r}} / \mathrm{m}_{\mathrm{o}}=0.014444$, and then, if denoting $\mathrm{N}^{*} \equiv \mathrm{~N}-$ $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, the optical band gap (OBG) is found to be given by:
$\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp} 1)}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right) \equiv \mathbb{E}_{\mathrm{gn} 2(\mathrm{gp} 2)}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right)+\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{~T}\right)$,
where the Fermi energy $\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{~T}\right)$ is determined in Eq. (A3) of the Appendix A and the reduced band gap is defined by:

$$
\mathbb{E}_{\mathrm{gn} 2(\mathrm{gp} 2)}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right) \equiv \mathbb{E}_{\mathrm{gnei}(\mathrm{gpei})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right)-\Delta \mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)
$$

Here, the effective intrinsic band gap $\mathbb{E}_{\text {gnei(gpei) }}$ is determined by:

$$
\mathbb{E}_{\text {gnei }(\text { gpei })}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right) \equiv \mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)-0.0935 \mathrm{eV} \times\left(\left[1+\left(\frac{2 T}{440.0613 K}\right)^{2.201}\right]^{\frac{1}{2.201}}-1\right)
$$

and the band gap narrowing, $\Delta \mathbb{E}_{\mathrm{gn}(\mathrm{gp)}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, are determined in Equations (B3, B4) of the Appendix B and the values of $\mathbb{E}_{\text {gni }(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ are given in Table 1. In particular, in the P-InSb crystal, one has; $\mathbb{E}_{\text {gnei }}\left(\mathrm{r}_{\mathrm{P}}, \mathrm{T}=300 \mathrm{~K}\right)=0.169779 \mathrm{eV}$.

Then, as noted in the Appendix A and B , at $\mathrm{T}=0 \mathrm{~K}$, as $\mathrm{N}^{*}=0$, one has: $\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{~T}\right)=\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}\right)=$ 0 , as given in Eq. (A4), and $\Delta \mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, according to the MIT, as noted in Appendix A and B. Therefore, $\mathbb{E}_{\operatorname{gn} 1(\mathrm{gp} 1)}=\mathbb{E}_{\mathrm{gn} 2(\mathrm{gp} 2)}=\mathbb{E}_{\mathrm{gnei}(\mathrm{gpei})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ at $\mathrm{T}=0 \mathrm{~K}$ and $\mathrm{N}^{*}=0$, according also to the MIT.

## 4. Physical model and mathematical methods

### 4.1. Physical model

In the $\mathrm{n}(\mathrm{p})$-type degenerate InSb , if denoting the Fermi wave number by: $\mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}(\mathrm{N}) \equiv\left(3 \pi^{2} \mathrm{~N} / \mathrm{g}_{\mathrm{c}(\mathrm{v})}\right)^{1 / 3}$, the effective reduced Wigner-Seitz radius $\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}$, characteristic of the interactions, is defined by
$\gamma \times \mathrm{r}_{\mathrm{sn}(\mathrm{sp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*}\right) \equiv \frac{\mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}^{-1}}{a_{\mathrm{Bn}(\mathrm{Bp})}}<1$,
being proportional to $\mathrm{N}^{*-1 / 3}$. Here, $\gamma=(4 / 9 \pi)^{1 / 3}, \mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}^{-1}$ means the averaged distance between ionized donors (acceptors), and $\mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is determined in Eq. (4).
Then, the ratio of the inverse effective screening length $\mathrm{k}_{\mathrm{sn}(\mathrm{sp})}$ to Fermi wave number $\mathrm{k}_{\mathrm{Fn}(\mathrm{kp})}$ at 0 K is defined by
$\mathrm{R}_{\mathrm{sn}(\mathrm{sp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \frac{\mathrm{k}_{\mathrm{sn}(\mathrm{sp})}}{\mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}}=\frac{\mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}^{-1}}{\mathrm{k}_{\mathrm{sn}(\mathrm{sp})}^{-1}}=\mathrm{R}_{\mathrm{snWS}(\mathrm{spWS})}+\left[\mathrm{R}_{\mathrm{snTF}(\mathrm{spTF})}-\mathrm{R}_{\mathrm{snWS}(\mathrm{spWS})} \times 0\right] e^{-\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}}<1$.
These ratios, $\mathrm{R}_{\mathrm{snTF}(\mathrm{spTF})}$ and $\mathrm{R}_{\mathrm{snWS}(\mathrm{spWS})}$, can be determined as follows.
First, for $N \gg \mathrm{~N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, according to the Thomas-Fermi (TF)-approximation, the ratio $\mathrm{R}_{\mathrm{snTF}(\mathrm{snTF})}$ is reduced to
$\mathrm{R}_{\mathrm{snTF}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \frac{\mathrm{k}_{\mathrm{smTF}(\mathrm{spTF})}}{\mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}}=\frac{\mathrm{k}_{\mathrm{rl}(\mathrm{Fp})}^{-1}}{\mathrm{k}_{\mathrm{snTF}(\mathrm{spTF})}^{-1}}=\sqrt{\frac{4 \gamma \mathrm{r}_{\mathrm{sn}(\mathrm{sp})}}{\pi}} \ll 1$,
being proportional to $\mathrm{N}^{-1 / 6}$.
Secondly, for $N<\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, according to the Wigner-Seitz (WS)-approximation, the ratio $\mathrm{R}_{\text {snWS(snWS) }}$ is respectively reduced to
$R_{\operatorname{sn}(\mathrm{sp}) \mathrm{WS}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \frac{\mathrm{k}_{\mathrm{sn}(\mathrm{sp}) \mathrm{WS}}}{\mathrm{k}_{\mathrm{Fn}}}=0.03(1.04) \times\left(\frac{3}{2 \pi}-\gamma \frac{\mathrm{d}\left[r_{\operatorname{sn}(\mathrm{sp})}^{2} \times \mathbb{E}_{\mathrm{CE}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)\right]}{\mathrm{d} r_{\operatorname{sn}(\mathrm{sp})}}\right)$,
where $\mathbb{E}_{C E}\left(\mathrm{~N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is the majority-carrier correlation energy (CE), being determined in Eq. (B2) of the Appendix B.

Furthermore, in the highly degenerate case, the physical conditions are found to be given by :
$\frac{\mathrm{k}_{\mathrm{Fr}(\mathrm{Fp})}^{-1}}{\mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}}<\frac{\eta_{\mathrm{n}(\mathrm{p})}}{\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}} \equiv \frac{1}{\mathrm{~A}_{\mathrm{n}(\mathrm{p})}}<\frac{\mathrm{k}_{\mathrm{Fr}(\mathrm{Fp})}^{-1}}{\mathrm{k}_{\mathrm{sn}(\mathrm{sp})}^{-1}} \equiv \mathrm{R}_{\mathrm{sn}(\mathrm{sp})}<1, \mathrm{~A}_{\mathrm{n}(\mathrm{p})} \equiv \frac{\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}}{\eta_{\mathrm{n}(\mathrm{p})}}$,
being needed to determine the expression for optical coefficients, as those investigated in Section 5. Here, $R_{s n(s p)}$ is defined in Eq. (7).

Then, in degenerate $\mathrm{d}(\mathrm{a})-\mathrm{InSb}$ systems, the total screened Coulomb impurity potential energy due to the attractive interaction between an electron(hole) charge, $-q(+q)$, at position $\overrightarrow{\mathrm{r}}$, and an ionized donor (ionized acceptor) charge: $+\mathrm{q}(-\mathrm{q})$ at position $\overrightarrow{\mathrm{R}_{\mathrm{j}}}$, randomly distributed throughout the InSb - crystal, is defined by $\mathrm{V}(\mathrm{r}) \equiv \sum_{\mathrm{j}=1}^{\mathbb{N}} \mathrm{v}_{\mathrm{j}}(\mathrm{r})+\mathrm{V}_{\mathrm{o}}$,
where $\mathbb{N}$ is the total number of ionized donors(acceptors), $\mathrm{V}_{\mathrm{o}}$ is a constant potential energy, and $\mathrm{v}_{\mathrm{j}}(\mathrm{r})$ is a screened Coulomb potential energy for each $d(a)$ - InSb system, defined as
$\mathrm{v}_{\mathrm{j}}(\mathrm{r}) \equiv-\frac{\mathrm{q}^{2} \times \exp \left(-\mathrm{k}_{\mathrm{sn}(\mathrm{sp}} \times\left|\mathrm{r}-\overrightarrow{\mathrm{R}}_{\mathrm{j}}\right|\right)}{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \times\left|\mathrm{Fr}-\overrightarrow{\mathrm{R}}_{\mathrm{j}}\right|}$,
where $\mathrm{k}_{\mathrm{sn}(\mathrm{sp})}$ is the inverse screening length determined in Eq. (7).
Further, using a Fourier transform, the $v_{j}$-representation in wave vector $\overrightarrow{\mathrm{k}}$-espace is given by
$\mathrm{v}_{\mathrm{j}}(\overrightarrow{\mathrm{k}})=-\frac{\mathrm{q}^{2}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)} \times \frac{4 \pi}{\Omega} \times \frac{1}{\mathrm{k}^{2}+\mathrm{k}_{\mathrm{sn}}^{2}}$,
where $\Omega$ is the total InSb -crystal volume.
Then, the effective auto-correlation function for potential fluctuations, $W_{n(p)}\left(v_{n(p)}, N^{*}, r_{d}\right) \equiv\left\langle V(r) V\left(r^{\prime}\right)\right\rangle$, was determined in II, as :

Here, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ is determined in Eq. (2), $\mathrm{R}_{\mathrm{sn}(\mathrm{sp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ in Eq. (7), the empirical Heisenberg parameter $\mathcal{H}=$ 3 (1.5), respectively, will be chosen such that the determination of the density of electrons localized in the conduction(valence)-band tails, determined in Section 5 would be accurate, and finally $v_{\mathrm{n}(\mathrm{p})} \equiv \frac{-\mathbb{E}}{\mathbb{E}_{\mathrm{Fro}(\mathrm{Fpo})}}$, where $\mathbb{E}$ is the total electron energy and $\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}$ is the Fermi energy at 0 K , determined in Eq. (A4) of the Appendix A.
In the following, we will calculate the ensemble average of the function: $(\mathbb{E}-V)^{a-\frac{1}{2}} \equiv \mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}$, for $\mathrm{a} \geq 1$, $\mathbb{E}_{\mathrm{k}} \equiv \frac{\hbar^{2} \times \mathrm{k}^{2}}{2 \times m_{n(p)}^{*}}$ being the kinetic energy of the electron (hole), and V(r) determined in Eq. (11), by using the two following integration methods, as developed in II, which strongly depend on $W_{n(p)}\left(v_{n(p)}, N^{*}, r_{d(a)}\right)$.

### 4.2. Mathematical methods and their application (Critical impurity density)

## A. Kane integration method (KIM)

In heavily doped $d(a)-$ InSb systems, the effective Gaussian distribution probability is defined by

$$
\mathrm{P}(\mathrm{~V}) \equiv \frac{1}{\sqrt{2 \pi W_{\mathrm{n}(\mathrm{p})}}} \times \exp \left[\frac{-\mathrm{V}^{2}}{\left.2 \mathrm{~W}_{\mathrm{n}(\mathrm{p}}\right)}\right]
$$

So, in the Kane integration method, the Gaussian average of $(\mathbb{E}-V)^{a-\frac{1}{2}} \equiv \mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}$ is defined by
$\left\langle(\mathbb{E}-V)^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}} \equiv\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}}=\int_{-\infty}^{\mathbb{E}}(\mathbb{E}-V)^{\mathrm{a}-\frac{1}{2}} \times \mathrm{P}(\mathrm{V}) \mathrm{dV}$, for $\mathrm{a} \geq 1$.

Then, by variable changes: $s=(\mathbb{E}-V) / \sqrt{W_{n(p)}}$ and $x=-\mathbb{E} / \sqrt{W_{n(p)}} \equiv A_{n(p)} \times v_{n(p)} \times \exp \left(\frac{\mathcal{H} \times R_{\operatorname{sn(sp)}}}{4 \times \sqrt{\left|v_{n(p)}\right|}}\right)$, and using an identity:
$\int_{0}^{\infty} s^{a-\frac{1}{2}} \times \exp \left(-x s-\frac{s^{2}}{2}\right) d s \equiv \Gamma\left(a+\frac{1}{2}\right) \times \exp \left(x^{2} / 4\right) \times D_{-a-\frac{1}{2}}(x)$,
where $D_{-a-\frac{1}{2}}(x)$ is the parabolic cylinder function and $\Gamma\left(a+\frac{1}{2}\right)$ is the Gamma function, one thus has:
$\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}}=\frac{\exp \left(-\mathrm{x}^{2} / 4\right) \times \mathrm{W}_{\mathrm{n}(\mathrm{p})}^{\frac{2 \mathrm{a}-1}{4}}}{\sqrt{2 \pi}} \times \Gamma\left(\mathrm{a}+\frac{1}{2}\right) \times \mathrm{D}_{-\mathrm{a}-\frac{1}{2}}(\mathrm{x})=\frac{\exp \left(-\mathrm{x}^{2} / 4\right) \times \eta_{\mathrm{n}(\mathrm{p})}^{\mathrm{a}-\frac{1}{2}}}{\sqrt{2 \pi}} \times \exp \left(-\frac{\mathcal{H} \times \mathrm{R}_{\operatorname{sn}(\mathrm{sp})} \times(2 \mathrm{a}-1)}{8 \times \sqrt{\left|v_{\mathrm{n}(\mathrm{p})}\right|}}\right) \times \Gamma(\mathrm{a}+$ $\left.\frac{1}{2}\right) \times D_{-a-\frac{1}{2}}(x)$.

## B. Feynman path-integral method (FPIM)

Here, the ensemble average of $(\mathbb{E}-V)^{a-\frac{1}{2}} \equiv \mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}$ is defined by
$\left\langle(\mathbb{E}-\mathrm{V})^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{FPIM}} \equiv\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{FPIM}} \equiv \frac{\hbar^{\mathrm{a}-\frac{1}{2}}}{2^{3 / 2} \times \sqrt{2 \pi}} \times \frac{\Gamma\left(\mathrm{a}+\frac{1}{2}\right)}{\Gamma\left(\frac{3}{2}\right)} \times \int_{-\infty}^{\infty}(i \mathrm{t})^{-\mathrm{a}-\frac{1}{2}} \times \exp \left\{\frac{i \mathbb{E} \mathrm{t}}{\hbar}-\frac{\left(\mathrm{t} \sqrt{W_{\mathrm{n}(\mathrm{p}}}\right)^{2}}{2 \hbar^{2}}\right\} \mathrm{dt}, \mathrm{i}^{2}=-1$,
noting that as $\mathrm{a}=1$, (it) $)^{-\frac{3}{2}} \times \exp \left\{-\frac{\left(\mathrm{t} \sqrt{W_{\mathrm{p}}}\right)^{2}}{2 \hbar^{2}}\right\}$ is found to be proportional to the averaged Feynman propagator given the dense donors(acceptors).
Then, by variable changes: $t=\frac{\hbar}{\sqrt{W_{n(p)}}}$ and $x=-\mathbb{E} / \sqrt{W_{n(p)}}$, and then using an identity:
$\int_{-\infty}^{\infty}(i s)^{-\mathrm{a}-\frac{1}{2}} \times \exp \left\{i x s-\frac{s^{2}}{2}\right\} \mathrm{ds} \equiv 2^{3 / 2} \times \Gamma(3 / 2) \times \exp \left(-\mathrm{x}^{2} / 4\right) \times \mathrm{D}_{-\mathrm{a}-\frac{1}{2}}(\mathrm{x})$,
one finally obtains: $\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{FPIM}} \equiv\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}},\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}}$ being determined in Eq. (13).
In the following, with use of asymptotic forms for $D_{-a-\frac{1}{2}}(x)$, those given for $\left\langle(\mathbb{E}-V)^{a-\frac{1}{2}}\right\rangle_{\text {KIM }}$ will be obtained in the two cases: $\mathbb{E} \geq 0$ and $\mathbb{E} \leq 0$.
(i) $\underline{E} \geq 0$-case

As $\mathbb{E} \rightarrow+\infty$, one has: $v_{\mathrm{n}} \rightarrow-\infty$ and $\mathrm{x} \rightarrow-\infty$. In this case, one gets:
$\mathrm{D}_{-\mathrm{a}-\frac{1}{2}}(\mathrm{x} \rightarrow-\infty) \approx \frac{\sqrt{2 \pi}}{\Gamma\left(\mathrm{a}+\frac{1}{2}\right)} \times e^{\frac{\mathrm{x}^{2}}{4}} \times(-\mathrm{x})^{\mathrm{a}-\frac{1}{2}}$.
Therefore, Eq. (13) becomes: $\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}} \approx \mathbb{E}^{\mathrm{a}-\frac{1}{2}}$. Further, as $\mathbb{E} \rightarrow+0$, one has: $v_{\mathrm{n}(\mathrm{p})} \rightarrow-0$ and $\mathrm{x} \rightarrow-\infty$. So, one gets :
$D_{-a-\frac{1}{2}}(x \rightarrow-\infty) \simeq \beta(a) \times \exp \left(\left(\sqrt{a}+\frac{1}{16 a^{\frac{3}{2}}}\right) x-\frac{x^{2}}{16 a}+\frac{x^{3}}{24 \sqrt{a}}\right) \rightarrow 0, \quad \beta(a)=\frac{\sqrt{\pi}}{2^{\frac{2 a+1}{4}}\left[\left(\frac{a}{2}+\frac{3}{4}\right)\right]}$.
Thus, as $\mathbb{E} \rightarrow+0$, from Eq. (13), one gets: $\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}} \rightarrow 0$.
In summary, for $\underline{\mathbb{E} \geq 0}$, the expression of $\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}}$ can be approximated by:
$\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}\right\rangle_{\mathrm{KIM}} \cong \mathbb{E}^{\mathrm{a}-\frac{1}{2}}, \quad \mathbb{E}_{\mathrm{k}} \equiv \frac{\hbar^{2} \times \mathrm{k}^{2}}{2 \times \mathrm{m}^{*}}$.
(ii) $\mathbb{E} \leq 0$ - case.

As $\mathbb{E} \rightarrow-0$, from Eq. (13), one has: $v_{\mathrm{n}(\mathrm{p})} \rightarrow+0$ and $\mathrm{x} \rightarrow+\infty$. Thus, one first obtains, for any a $\geq 1$,
$D_{-a-\frac{1}{2}}(x \rightarrow \infty) \simeq \beta(a) \times \exp \left[-\left(\sqrt{a}+\frac{1}{16 a^{\frac{3}{2}}}\right) x-\frac{x^{2}}{16 \mathrm{a}}-\frac{x^{3}}{24 \sqrt{2}}\right] \rightarrow 0, \beta(a)=\frac{\sqrt{\pi}}{\left.\left.2^{\frac{2 a+1}{4} \Gamma\left(\frac{a}{2}+\frac{3}{4}\right.}\right)\right]}$, noting that
$\beta(1)=\frac{\sqrt{\pi}}{2^{\frac{3}{4}} \times \Gamma(5 / 4)}$ and $\beta(5 / 2)=\frac{\sqrt{\pi}}{2^{3 / 2}}$.
Then, putting $f(a) \equiv \frac{\eta^{a}-\frac{1}{2}}{\eta_{n(p)}} \sqrt{2 \pi} \times \Gamma\left(a+\frac{1}{2}\right) \times \beta(a)$, Eq. (13) yields

Further, as $\mathbb{E} \rightarrow-\infty$, one has: $v_{\mathrm{n}(\mathrm{p})} \rightarrow+\infty$ and $\mathrm{x} \rightarrow \infty$. Thus, one gets:
$\mathrm{D}_{-\mathrm{a}-\frac{1}{2}}(\mathrm{x} \rightarrow \infty) \approx \mathrm{x}^{-\mathrm{a}-\frac{1}{2}} \times e^{-\frac{x^{2}}{4}} \rightarrow 0$. Therefore, Eq. (13) yields
$\mathrm{K}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})} \rightarrow+\infty, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right) \equiv \frac{\left\langle\mathbb{E}_{\mathrm{k}}^{\mathrm{a}-\frac{1}{2}}{ }_{\mathrm{K}}^{\mathrm{KIM}}\right.}{\mathrm{f}(\mathrm{a})} \simeq \frac{1}{\beta(\mathrm{a})} \times \exp \left(-\frac{\left(\mathrm{A}_{\mathrm{n}(\mathrm{p})} \times v_{\mathrm{n}(\mathrm{p})}\right)^{2}}{2}\right) \times\left(\mathrm{A}_{\mathrm{n}(\mathrm{p})} \times v_{\mathrm{n}(\mathrm{p})}\right)^{-\mathrm{a}-\frac{1}{2}} \rightarrow 0$.
It should be noted that, as $\mathbb{E} \leq 0$, the ratios (15) and (16) can be taken in an approximate form as:

$$
\begin{align*}
& \mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)=\mathrm{K}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)+\left[\mathrm{H}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)-\mathrm{K}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)\right] \times \exp \left[-\mathrm{c}_{1} \times\right. \\
& \left.\left(\mathrm{A}_{\mathrm{n}(\mathrm{p})} v_{\mathrm{n}(\mathrm{p})}\right)^{c_{2}}\right], \tag{17}
\end{align*}
$$

such that: $\mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right) \rightarrow \mathrm{H}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)$ for $0 \leq v_{\mathrm{n}} \leq 16$, and $\mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right) \rightarrow$ $\mathrm{K}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}\right)$ for $v_{\mathrm{n}(\mathrm{p})} \geq 16$. Here, the constants $\mathrm{c}_{1}$ and $\mathrm{c}_{2}$ may be respectively chosen as: $\mathrm{c}_{1}=10^{-40}$ and $c_{2}=80$, as $a=1$, being used to determine the critical density of electrons (holes) localized in the exponential conduction(valence) band-tails (EBT), $N_{C D n(C D p)}^{\mathrm{EBT}}\left(\mathrm{N}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, in the following.

## C. Critical impurity density in the MIT

In degenerate $\mathrm{d}(\mathrm{a})$ - InSb systems at $\mathrm{T}=0 \mathrm{~K}$, in which $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}=0.015$ (0.39), as given in Section 2, using Eq. (13), for $\mathrm{a}=1$, the density of states $\mathcal{D}(\mathbb{E})$ is defined by:
$\left\langle\mathcal{D}\left(\mathbb{E}_{\mathrm{k}}\right)\right\rangle_{\mathrm{KIM}} \equiv \frac{\mathrm{g}_{c(v}}{2 \pi^{2}}\left(\frac{2 m_{n(p)}}{\hbar^{2}}\right)^{\frac{3}{2}} \times\left\langle\mathbb{E}_{\mathrm{k}}^{\frac{1}{2}}\right\rangle_{\text {KIM }}=\frac{\mathrm{g}_{\mathrm{c}(\mathrm{v})}}{2 \pi^{2}}\left(\frac{2 \mathrm{~m}_{n(p)}}{\hbar^{2}}\right)^{\frac{3}{2}} \times \frac{\exp \left(-\frac{-x^{2}}{4}\right) \times W_{n}^{\frac{1}{4}}}{\sqrt{2 \pi}} \times \Gamma\left(\frac{3}{2}\right) \times \mathrm{D}_{-\frac{3}{2}}(\mathrm{x})=\mathcal{D}(\mathbb{E})$,
where x is defined in Eq. (13), as: $\mathrm{x}=-\mathbb{E} / \sqrt{\mathrm{W}_{\mathrm{n}(\mathrm{p})}} \equiv \mathrm{A}_{\mathrm{n}(\mathrm{p})} \times v_{\mathrm{n}(\mathrm{p})} \times \exp \left(\frac{\mathcal{H} \times \mathrm{R}_{\mathrm{sn}(\mathrm{sp})}}{4 \times \sqrt{\left|\operatorname{lnn}_{\mathrm{n}(\mathrm{p})}\right|}}\right)$.
Here, $\mathbb{E}_{\text {Fno }}$ is determined in Eq. (A4) of the Appendix A, with $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{n}(\mathrm{p})} / \mathrm{m}_{\mathrm{o}}$ and $\mathcal{H}=3$ (1.5), respectively, being chosen such that the following determination of $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{N}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ would be accurate.

Going back to the functions: $H_{n}, K_{n}$ and $F_{n}$, given respectively in Equations (15-17), in which the factor $\frac{\left\langle\mathbb{E}_{\mathrm{k}}^{\frac{1}{2}}\right\rangle_{\text {KIM }}}{\mathrm{f}(\mathrm{a}=1)}$ is now replaced by:
$\frac{\left\langle\mathbb{E}_{\mathrm{k}}^{\frac{1}{2}}\right\rangle_{\mathrm{KIM}}}{\mathrm{f}(\mathrm{a}=1)}=\frac{\mathcal{D}(\mathbb{E} \leq 0)}{\mathcal{D}_{0}}=\mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(\nu_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}=1\right), \mathcal{D}_{\mathrm{o}}=\frac{\mathrm{g}_{\mathrm{c}(\mathrm{v})} \times\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})} \times \mathrm{m}_{\mathrm{o}}\right)^{3 / 2} \times \sqrt{\eta_{\mathrm{n}(\mathrm{p})}}}{2 \pi^{2} \hbar^{3}} \times \beta(\mathrm{a}=1), \beta(\mathrm{a}=1)=\frac{\sqrt{\pi}}{2^{\frac{3}{4}} \times \Gamma(5 / 4)}$.

Therefore, $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{N}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ can be defined by
$N_{\text {CDn(CDp) }}^{\mathrm{EBT}}\left(\mathrm{N}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\int_{-\infty}^{0} \mathcal{D}(\mathbb{E} \leq 0) \mathrm{dE}$,
where $\mathcal{D}(\mathbb{E} \leq 0)$ is determined in Eq. (19). Then, by a variable change: $v_{\mathrm{n}(\mathrm{p})} \equiv \frac{-\mathbb{E}}{\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}}$, one obtains:
$N_{C D n(C D p)}^{\mathrm{EBT}}\left(\mathrm{N}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\frac{\mathrm{g}_{\mathrm{c}(\mathrm{v})} \times\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})}\right)^{3 / 2} \sqrt{\eta_{\mathrm{n}(\mathrm{p})} \times \mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}}}{2 \pi^{2} \hbar^{3}} \times\left\{\int_{0}^{16} \beta(\mathrm{a}=1) \times \mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}=1\right) \mathrm{d} v_{\mathrm{n}(\mathrm{p})}+\mathrm{I}_{\mathrm{n}(\mathrm{p})}\right\}$,
where
$\mathrm{I}_{\mathrm{n}(\mathrm{p})} \equiv \int_{16}^{\infty} \beta(\mathrm{a}=1) \times \mathrm{K}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}=1\right) \mathrm{d} v_{\mathrm{n}(\mathrm{p})}=\int_{16}^{\infty} e^{\frac{-\left(\mathrm{A}_{\mathrm{n}(\mathrm{p})} \times v_{\mathrm{n}}\right)^{2}}{2}} \times\left(\mathrm{A}_{\mathrm{n}(\mathrm{p})} v_{\mathrm{n}(\mathrm{p})}\right)^{-3 / 2} \mathrm{~d} v_{\mathrm{n}(\mathrm{p})}$.
Here, $\beta(\mathrm{a}=1)=\frac{\sqrt{\pi}}{2^{\frac{3}{4}} \times \Gamma(5 / 4)}$.
Then, by another variable change: $\mathrm{t}=\left[\mathrm{A}_{\mathrm{n}(\mathrm{p})} v_{\mathrm{n}(\mathrm{p})} / \sqrt{2}\right]^{2}$, the integral $\mathrm{I}_{\mathrm{n}(\mathrm{p})}$ yields:
$I_{n(p)}=\frac{1}{2^{5 / 4} A_{n(p)}} \times \int_{y_{n(p)}}^{\infty} t^{b-1} e^{-t} d t \equiv \frac{\Gamma\left(\mathrm{~b}, \mathrm{y}_{\mathrm{n}}(\mathrm{p})\right)}{2^{5 / 4} \times A_{\mathrm{n}(\mathrm{p})}}$,
where $\mathrm{b}=-1 / 4, \mathrm{y}_{\mathrm{n}(\mathrm{p})}=\left[16 \mathrm{~A}_{\mathrm{n}(\mathrm{p})} / \sqrt{2}\right]^{2}$, and $\Gamma\left(\mathrm{b}, \mathrm{y}_{\mathrm{n}(\mathrm{p})}\right)$ is the incomplete Gamma function, defined by:
$\Gamma\left(\mathrm{b}, \mathrm{y}_{\mathrm{n}(\mathrm{p})}\right) \simeq \mathrm{y}_{\mathrm{n}(\mathrm{p})}^{\mathrm{b}-1} \times e^{-\mathrm{y}_{\mathrm{n}(\mathrm{p})}}\left[1+\sum_{\mathrm{j}=1}^{16} \frac{(\mathrm{~b}-1)(\mathrm{b}-2) \ldots(\mathrm{b}-\mathrm{j})}{\mathrm{y}_{\mathrm{n}(\mathrm{p})}^{\mathrm{j}}}\right]$.
Finally, Eq. (20) now yields:
$\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left[\mathrm{N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right]=\frac{\mathrm{g}_{\mathrm{c}(\mathrm{v})} \times\left(\mathrm{m}_{\mathrm{n}(\mathrm{p})}\right)^{3 / 2} \sqrt{\eta_{\mathrm{n}(\mathrm{p})}} \times \mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}}{2 \pi^{2} \hbar^{3}} \times\left\{\int_{0}^{16} \beta(\mathrm{a}=1) \times\right.$
$\left.\mathrm{F}_{\mathrm{n}(\mathrm{p})}\left(v_{\mathrm{n}(\mathrm{p})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{a}=1\right) \mathrm{d} v_{\mathrm{n}(\mathrm{p})}+\frac{\Gamma\left(\mathrm{b}, y_{\mathrm{n}(\mathrm{p})}\right)}{2^{5 / 4} \times \mathrm{A}_{\mathrm{n}(\mathrm{p})}}\right\}$,
being the density of electrons(holes) localized in the exponential conduction(valence)-band tails (EBT), respectively.
The numerical results of $N_{C D n(C D p)}^{E B T}\left[N=N_{C D n(N D p)}\left(r_{d(a)}\right), r_{d(a)}\right] \equiv N_{C D n(C D p)}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, for a simplicity of presentation, evaluated using Eq. (21), are given in Table 1, confirming thus those of $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, calculated using Eq. (3), with a precision of the order of $7.8 \%$ (11\%), respectively. In other word, this critical $\mathrm{d}(\mathrm{a})$-density $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a}))}\right)$ can thus be explained by the density of electrons(holes) localized in the EBT, $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$.

So, the effective density of free electrons (holes), $\mathrm{N}^{*}$, given in the parabolic conduction (valence) band of the degenerate $\mathrm{d}(\mathrm{a})-\mathrm{InSb}$ systems, can thus be expressed by:
$\mathrm{N}^{*} \equiv \mathrm{~N}-\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})} \cong \mathrm{N}-\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}$.
Then, if $\mathrm{N}^{*}=\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}$, according to the Fermi energy, $\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}=\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\right) \equiv \frac{\hbar^{2} \times \mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}^{2}\left(\mathrm{~N}^{*}\right)}{2 \times \mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*}}$, the value of the density of electrons(holes), $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}}$, localized in the EBT for $\mathbb{E} \leq 0$, is almost equal to $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}$, given in this parabolic conduction (valence) band, for $\mathbb{E} \geq 0$. This can thus be expressed as:
$\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}} \cong \mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}$, as $\mathrm{N}^{*} \equiv \mathrm{~N}_{\mathrm{CDn}(\mathrm{NDp})}$.

## 5. Optical coefficients

Here, $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}$ is chosen as: $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{r}} / \mathrm{m}_{\mathrm{o}}=0.014444$, as that used in Section 3, for determining the optical band gap in degenerate InSb -crystals.
The optical properties of any medium can be described by the complex refraction index $\mathbb{N}$ and the complex dielectric function $\varepsilon, \mathbb{N} \equiv \mathrm{n}-\mathrm{i} \kappa$ and $\varepsilon \equiv \varepsilon_{1}-\mathrm{i} \varepsilon_{2}$, where $\mathrm{i}^{2}=-1$ and $\varepsilon \equiv \mathbb{N}^{2}$. Therefore, the real and imaginary parts of $\varepsilon$ denoted by $\varepsilon_{1}$ and $\varepsilon_{2}$ can thus be expressed in terms of the refraction index $n$ and the extinction coefficient $\kappa$ as: $\varepsilon_{1} \equiv \mathrm{n}^{2}-\kappa^{2}$ and $\varepsilon_{2} \equiv 2 n \kappa$. One notes that the optical absorption coefficient $\alpha$ is related to $\varepsilon_{2}, \mathrm{n}, \kappa$, and the optical conductivity $\sigma_{0}$ by [3]
$\alpha(\mathrm{E}) \equiv \frac{\hbar \mathrm{q}^{2} \times|\mathrm{v}(\mathrm{E})|^{2}}{\mathrm{n}(\mathrm{E}) \times \varepsilon_{\text {free space }} \times \mathrm{cE}} \times \mathrm{J}\left(\mathrm{E}^{*}\right)=\frac{\mathrm{E} \times \varepsilon_{2}(\mathrm{E})}{\hbar \mathrm{cn}(\mathrm{E})} \equiv \frac{2 \mathrm{E} \times \kappa(\mathrm{E})}{\hbar c} \equiv \frac{4 \pi \sigma_{0}(\mathrm{E})}{\mathrm{cn}(\mathrm{E}) \times \varepsilon_{\text {free }} \text { space }}, \varepsilon_{1} \equiv \mathrm{n}^{2}-\kappa^{2}$ and $\varepsilon_{2} \equiv 2 \mathrm{n} \kappa$,
where the effective photon energy: $\mathrm{E}^{*}=\mathrm{E}-\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}=\mathbb{E}$ is the reduced photon energy, the band gap $\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}$ can be equal to the optical band gap $\mathbb{E}_{\operatorname{gn} 1(\mathrm{gp1})}$, the effective intrinsic band gap $\mathbb{E}_{\text {gnei(gpei) }}$, or to the intrinsic band gap $\mathbb{E}_{\text {gni(gpi) }}$, determined in Eq. (5). Here, $E \equiv \hbar \omega,-q, \hbar,|v(E)|, \omega, \varepsilon_{\text {free space }}, c$ and $J\left(E^{*}\right)$ respectively represent: the photon energy, electron charge, Dirac's constant, matrix elements of the velocity operator between valence (conduction)-and-conduction (valence) bands in $n(p)$-type InSb-semiconductors, photon frequency, permittivity of free space, velocity of light, and joint density of states. It should be noted that, if the three functions such as: $|v(E)|^{2}, J\left(E^{*}\right)$ and $n(E)$ are known, then the other optical dispersion functions given in Eq. (24) can thus be determined. Moreover, the normal-incidence reflectance, $R(E)$, can be expressed in terms of $\kappa(E)$ and $n(E)$ as:
$R(E)=\frac{[n(E)-1]^{2}+k(E)^{2}}{[n(E)+1]^{2}+\kappa(E)^{2}}$.
From Equations $(24,25)$, if the two optical functions, $\varepsilon_{1}$ and $\varepsilon_{2}$, (or $n$ and $\kappa$ ), are both known, the other ones defined above can thus be determined.

Then, using a transformation for the joint density of states, $\mathrm{J}\left(\mathrm{E}^{*}\right)$, given in allowed direct InSb -transitions, one obtains: at low values of $\mathrm{E}, \mathbb{E}_{\text {gni(gpi) }} \leq \mathrm{E} \leq 1.6 \mathrm{eV}$, and for $a=\frac{5.4415}{2}$,
$\mathrm{J}_{\mathrm{n}(\mathrm{p})}\left(\mathrm{E}^{*}\right)=\frac{1}{2 \pi^{2}} \times\left(\frac{2 \mathrm{~m}_{\mathrm{r}}}{\hbar^{2}}\right)^{3 / 2} \times \mathrm{E}_{\mathrm{gni}(\mathrm{gpi})}^{1-\mathrm{a}} \times\left(\mathrm{E}-\mathrm{E}_{\mathrm{gn}(\mathrm{gp})}\right)^{\mathrm{a}-(1 / 2)}=\frac{1}{2 \pi^{2}} \times\left(\frac{2 \mathrm{~m}_{\mathrm{r}}}{\hbar^{2}}\right)^{3 / 2} \times \mathrm{E}_{\mathrm{gni}(\mathrm{gpi})}^{\frac{-3.4415}{2}} \times\left(\mathrm{E}-\mathrm{E}_{\mathrm{gn}(\mathrm{gp})}\right)^{\frac{4.4415}{2}}$,
and, at large values of $\mathrm{E}, \mathrm{E} \geq 1.6 \mathrm{eV}$ and for $\mathrm{a}=5 / 2$,

$$
\begin{equation*}
\mathrm{J}_{\mathrm{n}(\mathrm{p})}\left(\mathrm{E}^{*}\right)=\frac{1}{2 \pi^{2}} \times\left(\frac{2 \mathrm{~m}_{\mathrm{r}}}{\hbar^{2}}\right)^{3 / 2} \times \frac{\left(\mathrm{E}-\mathrm{E}_{\mathrm{gn}(\mathrm{gp})}\right)^{\mathrm{a}-(1 / 2)}}{\mathrm{E}_{\mathrm{gni}(\mathrm{gpi})}^{-1}}=\frac{1}{2 \pi^{2}} \times\left(\frac{2 \mathrm{~m}_{\mathrm{r}}}{\hbar^{2}}\right)^{3 / 2} \times \frac{\left(\mathrm{E}-\mathbb{E}_{\mathrm{gn}(\mathrm{gp}))^{2}}\right.}{\mathrm{E}_{\mathrm{gni}(\mathrm{gpi})}^{3 /}} \tag{27}
\end{equation*}
$$

Further, one notes that, as $\mathrm{E} \rightarrow \infty$, Forouhi and Bloomer (FB) [11] claimed that $\kappa(\mathrm{E} \rightarrow \infty) \rightarrow$ a constant, while the $\kappa(E)$-expressions, proposed by Jellison and Modine [12] and by Van Cong [3] quickly go to 0 as $E^{-3}$, and consequently, their numerical results of the optical functions such as: $\sigma_{0}(E)$ and $\alpha(E)$, given in Eq. (24), both go 0 as $\mathrm{E}^{-2}$.

Now, taking into account Equations $(26,27)$ and also those remarks, an improved Forouhi-Bloomer parameterization model (IFB-PM), used to determine the accurate expressions of the optical coefficients, obtained in the degenerate $n(p)$ type InSb-crystals, is proposed as follows.

If, defining the band gap $\mathbb{E}_{\mathrm{gn}(\mathrm{gp})}$, which can be equal to the optical band gap $\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp} 1)}$, the effective intrinsic band gap $\mathbb{E}_{\text {gnei(gpei) }}$, or to the intrinsic band gap $\mathbb{E}_{\text {gni(gpi) }}$, determined in Equations $(1,5)$, and defining the function: $f(E) \equiv \sum_{i=1}^{4} \frac{A_{i}}{g(E)-B_{i} E+C_{i}}$, where $g(E)=E^{2} \times\left(1+10^{-4} \times \frac{E}{6}\right)$, we propose:

$$
\begin{align*}
\kappa\left(E^{*}\right) & =f(E) \times \mathbb{E}_{\text {gni }(\mathrm{gpi})}^{\frac{-0.4415}{2}} \times\left(E^{*} \equiv E-\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp} 1)}\right)^{\frac{4.4415}{2}}, \text { for } \mathbb{E}_{\text {gni(gpi) }} \leq E \leq 1.6 \mathrm{eV} \\
& =f(E) \times\left(E^{*} \equiv E-\mathbb{E}_{\operatorname{gn} 1(\mathrm{gp} 1)}\right)^{2}, \text { for } E \geq 1.6 \mathrm{eV} \tag{28}
\end{align*}
$$

being equal to 0 for $E^{*}=0$ (or for $E=\mathbb{E}_{\operatorname{gn} 1(g p 1)}$ ), and also going to 0 as $E^{-1}$ as $E \rightarrow \infty$, and further,
$n(E)=n_{\infty}\left(r_{d(a)}\right)+\sum_{i=1}^{4} \frac{B_{0 i} E+C_{o i}}{E^{2}-B_{i} E+C_{i}}$,
going to a constant, as $\mathrm{E} \rightarrow \infty, \mathrm{n}\left(\mathrm{E} \rightarrow \infty, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\mathrm{n}_{\infty}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\sqrt{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)} \times \frac{\omega_{\mathrm{T}}}{\omega_{\mathrm{L}}}, \omega_{\mathrm{T}}=3.5 \times 10^{13} \mathrm{~s}^{-1}$ and $\omega_{\mathrm{L}}=8.935675 \times 10^{13} \mathrm{~s}^{-1}$, obtained from the Lyddane-Sachs-Teller relation [5], from which $\mathrm{T}(\mathrm{L})$ represents the transverse (longitudinal) optical phonon mode, so that, in the P-InSb system, in which $\mathbb{E}_{\text {gni }}\left(r_{P}\right)=0.2298 \mathrm{eV}$, we obtain: $\mathrm{n}_{\infty}\left(\mathrm{r}_{\mathrm{P}}\right)=1.755$, while, in the $\mathrm{FB}-\mathrm{PM}[11], \mathrm{n}_{\infty(\mathrm{FB}-\mathrm{PM})}=1.803$ and the band gap $E_{g(F M-P M)}=0.12 \mathrm{eV}<\mathbb{E}_{\text {gni }(\text { gpi })}$, as observed in Table 1. Here, $\mathrm{B}_{\mathrm{oi}}\left(\mathrm{E}_{\text {gnei }(\text { gpei })}\right)=\frac{A_{i}}{Q_{i}} \times\left[-\frac{B_{i}^{2}}{2}+\right.$
$\left.E_{\text {gnei(gpei) }} B_{i}-E_{\text {gnei(gpei) }}^{2}+C_{i}\right], C_{o i}\left(E_{\text {gnei(gpei) }}\right)=\frac{A_{i}}{Q_{i}} \times\left[\frac{B_{i} \times\left(E_{\text {gnei(gpei) }}^{2}+C_{i}\right)}{2}-2 \mathbb{E}_{\text {gnei(gpei) }} C_{i}\right], Q_{i}=\frac{\sqrt{4 C_{i}-B_{i}^{2}}}{2}$, where, for $i=\left(1,2,3\right.$, and 4), the numerical values of the parameters for the $\operatorname{InSb}$-crystal, such as: $A_{i}, B_{i}$, and $C_{i}$, are given in Ref. [11], as used in the FB-PM.
The important numerical results of the above optical functions, at $\mathrm{T}=0 \mathrm{~K}, \mathrm{~N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}$, and for $\mathrm{E}=\mathbb{E}_{\text {gni }}$ (gi) , are reported in following Tables $2 \mathrm{a}, 2 \mathrm{~b}$ and 2 c , and Tables $3 \mathrm{a}, 3 \mathrm{~b}$ and 3 c , in which they are also compared with the corresponding ones, calculated using from FB-PM [11], and also the relative deviations (RDs) of those numerical results, calculated using the corresponding data, given by Aspnes and Studna [9], suggesting that our obtained numerical results of these optical coefficients are found to be more accurate than the corresponding ones, obtained from the FB-PM, as observed in Table 3c.

Table 2a. At the MIT, $T=0 K, N=N_{\operatorname{CDn}(\mathrm{p})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, and the critical photon energy $\mathrm{E}_{\mathrm{CPE}}=\mathrm{E}=\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathrm{K}_{\mathrm{MIT}}\left(\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, $\varepsilon_{2(\operatorname{MIT})}\left(\mathbb{E}_{\text {gni }(\text { gpi })}, r_{d(a)}\right)=0, \sigma_{0(\text { miT })}\left(\mathbb{E}_{\text {gni (gpi) }}, r_{d(a)}\right)=0$ and $\propto_{\text {MIT }}\left(\mathbb{E}_{\text {gni (gpi) }}, r_{d(a)}\right)=0$, and the other functions such as : $\mathrm{n}_{\text {MIT }}\left(\mathbb{E}_{\text {gni }(\text { gpi })}, r_{d(a)}\right), \varepsilon_{1(\mathrm{MIT})}\left(\mathbb{E}_{\text {gni }(\text { gpi })}, r_{d(a)}\right)$, and $\mathrm{R}_{\text {MIT }}\left(\mathbb{E}_{\text {gni (gpi) }}, r_{d(a)}\right)$ decrease, with increasing $r_{d(a)}$ and $\mathbb{E}_{\text {gni }}\left(r_{d(a)}\right)$.

Table 3b. In the P-InSb system, at $\mathrm{T}=0 \mathrm{~K}$, our numerical results of the following optical coefficients, expressed as functions of E , and calculated using Equations $(24,25,28,29)$, for $\mathbb{E}_{\mathrm{gn}}\left(\mathrm{r}_{\mathrm{P}}\right)=\mathbb{E}_{\mathrm{gni}}\left(\mathrm{r}_{\mathrm{P}}\right)[=0.2298 \mathrm{eV}]$, and the corresponding ones, obtained from the FB-model [11], are reported in this Table 3b, in which the relative deviations (RDs) of those are also given and calculated, using the AS-data [9]. Here, as reported in above Table 2c, one also obtains here: $\alpha_{\infty}\left(E \rightarrow \infty, r_{P}\right)=2.0116 \times 10^{9} \mathrm{~cm}^{-1}$ and $\sigma_{0, \infty}(E \rightarrow$ $\left.\infty, r_{P}\right)=7.457275 \times 10^{5}\left(\frac{1}{\Omega \times c \mathrm{~cm}}\right)$, while, in the FB-model, $\propto_{\mathrm{FB}} \rightarrow \infty$, and $\sigma_{0(\mathrm{FB})} \rightarrow \infty$, which should be not correct.

| E in eV | $\propto\left(10^{3} \times \mathrm{cm}^{-1}\right) ; \mathrm{RD} \%$ | R; RD\% | $\sigma_{O}\left(\frac{1}{\Omega \times c m}\right)$ | $\sigma_{O(F B)}\left(\frac{1}{\Omega \times c m}\right)$ | $\propto_{F B}\left(10^{3} \times c m^{-1}\right) ; \mathrm{RD}^{\prime}$ | $R_{F B} ; \mathrm{RD} \%$ |

$\qquad$
Some important cases, given in various physical conditions, are considered as follows.

### 5.1. Metal-insulator transition (MIT)-case

As discussed in Equations (21-23) and Eq. (A4) of the Appendix A, the physical conditions used for the MIT are: $\quad \mathrm{T}=0 \mathrm{~K}, \quad \mathrm{~N}^{*}=0 \quad$ or $\quad \mathrm{N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})} \cong \mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}^{\mathrm{EBT}} \quad$, vanishing the Fermi energy: $\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}\right) \equiv \frac{\hbar^{2} \times \mathrm{k}_{\mathrm{Fn}(\mathrm{Fp})}^{2}\left(\mathrm{~N}^{*}\right)}{2 \times \mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*}}=0$. Further, from the discussions given Eq . (5) for the optical band gap: $\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp} 1)}\left(\mathrm{N}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}=0\right)=\mathbb{E}_{\mathrm{gnei}(\mathrm{gpei})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, according also to the MIT . Then, in such the MIT-case, replacing both $\mathbb{E}_{\text {gnei(gpei) }}$ and $\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp1})}$, by $\mathbb{E}_{\text {gni(gpi) }}$, given in Equations $(28,29)$, and consequently from Eq. (24), one gets, for the effective photon energy $\mathrm{E}^{*} \equiv \mathrm{E}-\mathbb{E}_{\text {gni(gpi) }}=0$ :
$\kappa\left(\mathrm{E}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0, \varepsilon_{2}\left(\mathrm{E}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0, \sigma_{0}\left(\mathrm{E}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$ and $\alpha\left(\mathrm{E}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, corresponding also to the MIT. Thus, in this case, the photon energy E becomes the critical photon energy, defined by:

$$
\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}^{\frac{-0.4415}{2}} \times\left(\mathrm{E}^{*} \equiv \mathrm{E}-\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}=0\right)^{\frac{4.4415}{2}}
$$

$\mathrm{E}_{\mathrm{CPE}}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv \mathbb{E}_{\text {gni }(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$. Therefore, Equations $(28,29)$, obtained in the MIT-case, become:
$\kappa\left(\mathrm{E}^{*}=0\right)=\mathrm{f}(\mathrm{E}) \times \mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}^{\frac{-0.4415}{2}} \times\left(\mathrm{E}^{*} \equiv \mathrm{E}-\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\right)^{\frac{4.4415}{2}}=0$, for $\mathrm{E}=\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}<1.6 \mathrm{eV}$,
and
$\mathrm{n}\left(\mathrm{E}=\mathbb{E}_{\text {gni }(\text { gpi })}\right)=\mathrm{n}_{\infty}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)+\sum_{\mathrm{i}=1}^{4} \frac{\mathrm{~B}_{\mathrm{oi}} \mathrm{E}+\mathrm{C}_{\mathrm{oi}}}{\mathrm{E}^{2}-\mathrm{B}_{\mathrm{i}} \mathrm{E}+\mathrm{C}_{\mathrm{i}}}$, in which $\mathbb{E}_{\text {gnei }(\text { gpei })}=\mathbb{E}_{\text {gni }(\mathrm{gpi})}$.
Then, going back to the remark given in Eq. (23), we can determine the values of some optical coefficients for $\mathbb{E} \leq 0$, representing the exponential tail-states, from Eq. (30), by putting: $\mathbb{E}^{*}=\mathbb{E}_{\text {gni }(\mathrm{gpi})}$, as:
$\kappa^{\mathrm{EEC}-\mathrm{T}}\left(\mathbb{E}_{\text {gni }(\mathrm{gpi})}\right)=\mathrm{f}\left(\mathrm{E}_{\text {gni }(\mathrm{gpi})}\right) \times \mathbb{E}_{\text {gni }(\text { gpi })}^{2}$.
Now, replacing Equations $(31,32)$ into Equations $(24,25)$, one obtains for $\mathbb{E} \leq 0$ the expressions, given for the following exponential tail-states of $\varepsilon_{2}, \sigma_{0}(E), \alpha$, and $R$ as:

$$
\begin{align*}
& \varepsilon_{2}^{\text {EImD-T }}\left(\mathbb{E}_{\text {gni }} \text { (gpi) }\right)=2 \times \kappa^{\text {EEC-T }}\left(\mathbb{E}_{\text {gni }(\text { gpi })}\right) \times \mathrm{n}^{\text {ERI-T }}\left(\mathrm{E}=\mathbb{E}_{\text {gni(gpi) }}\right),  \tag{33}\\
& \left.\sigma_{0}^{\text {EOC-T }}\left(\mathbb{E}_{\text {gni }}(\mathrm{gpi})\right)=\frac{\varepsilon_{\text {free space }} \times \mathbb{E}_{\text {gni }}(\text { gpi }) \times \varepsilon_{2}^{\text {EImD }-T}\left(\mathbb{E}_{\text {gni }}(\text { gpi })\right.}{}\right),  \tag{34}\\
& \alpha^{\mathrm{EOAC}-\mathrm{T}}\left(\mathbb{E}_{\text {gni }(\mathrm{gpi})}\right)=\frac{2 \times \mathbb{E}_{\text {gni }}(\text { gpi })}{} \times \kappa^{\mathrm{EEC}-\mathrm{T}}\left(\mathbb{E}_{\text {gni(gpi) }}\right) \text {, and } \tag{35}
\end{align*}
$$

The numerical results of those optical functions, determined by Equations (31-36, 24), were discussed and reported in the above Table 2 b .

### 5.2. Extrema values of $\boldsymbol{\varepsilon}_{1(2)}$ as functions of photon energy $E$

From Equations $(24,28,29)$, we can determine the extrema values of typical optical functions $\varepsilon_{1(2)}\left(E, r_{d(a)}\right)$ in following physical conditions by: $\mathrm{T}=0 \mathrm{~K}$ and $\mathrm{N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}$, and by: $\mathrm{T}=20 \mathrm{~K}$ and $\mathrm{N}=10^{19} \mathrm{~cm}^{-3}$, respectively, as given in following Tables 4 n and 4 p , in which the arrows $(\uparrow \downarrow)$ indicates the maximum, and $(\downarrow \uparrow)$ the minimum and the extrema-values of those occur at the same corresponding photon energy E.

Table 4n. In d-InSb systems, and for two types of physical conditions such as: $\left[\mathrm{T}=0 \mathrm{~K}\right.$ and $\left.\mathrm{N}=\mathrm{N}_{\mathrm{CDn}}\left(\mathrm{r}_{\mathrm{d}}\right)\right]$ and $[\mathrm{T}=20 \mathrm{~K}, \mathrm{~N}=$ $\left.10^{19} \mathrm{~cm}^{-3}\right]$, the extrema values of $\varepsilon_{1}(\mathrm{E})$ and $\varepsilon_{2}(\mathrm{E})$, calculated using Equations $(24,28,29)$, vary with increasing E , represented by the arrows: $\uparrow$ or $\downarrow$, suggesting that those extrema occur at the same E.

### 5.3. Variations of various optical coefficients as functions of $N$, typically for some $d(a)-I n S b$ systems

Also, from Equations $(24,28,29)$, we can determine the variations of various optical coefficients at 20 K , as functions of N , at $\mathrm{E}=3.3 \mathrm{eV}$, for example, and for some $(\mathrm{P}, \mathrm{Te}, \mathrm{Sn})-\mathrm{InSb}$ systems and for some $(\mathrm{Ga}, \mathrm{In})-\mathrm{InSb}$
ones, being indicated by the arrows: $\nearrow$ and $\downarrow$, as tabulated in following Tables 5 n and 5 p , in which the physical condition $\mathrm{N}>\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}$ (or $\mathrm{N}^{*}>0$ ) must be respected, and their variations thus depend on the ones of the optical band gap, $\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp} 1)}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$.

Table 5n. In (P, Te, Sn)- InSb systems, our numerical results of the following optical coefficients, expressed as functions of N , and calculated using Equations (31-36, 24), for $\mathrm{E}=3.3 \mathrm{eV}$ and $\mathrm{T}=20 \mathrm{~K}$, present the variations by arrows, ( $\downarrow$ and $\nearrow$ ), since those of the optical gap $\mathbb{E}_{\mathrm{gn1}}\left(\mathrm{~N}^{*}, \mathrm{r}_{\mathrm{d}}\right)$ increase with increasing N , at $\mathrm{T}=20 \mathrm{~K}$.

### 5.4. Variations of various optical coefficients as functions of T, typically for some d(a)- InSb systems

Here, from Equations (24, 28, 29), we can determine the variations of various optical coefficients at $\mathrm{N}=$ $1.5 \times 10^{19} \mathrm{~cm}^{-3}$, respectively, as functions of T , at $\mathrm{E}=3.3 \mathrm{eV}$, for example, and for some $(\mathrm{P}, \mathrm{Te}, \mathrm{Sn})-\mathrm{InSb}$ systems and for some (Ga, In)- InSb ones, being indicated by the arrows: $\nearrow$ and $\searrow$, as given in following Tables 6 n and 6 p , in which their variations thus depend on the ones of the optical band gap, $\mathbb{E}_{\mathrm{gn1} 1 \mathrm{gp1})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$.

Table 6n. In (P, Te, Sn )- InSb systems, our numerical results of the following optical coefficients, expressed as functions of T, and calculated using Equations (31-36, 24), for $\mathrm{E}=3.3 \mathrm{eV}$ and $\mathrm{N}=1.5 \times 10^{19} \mathrm{~cm}^{-3}$, increase with increasing T , since the optical band gap $\mathbb{E}_{\mathrm{gn} 1}\left(\mathrm{~T}, \mathrm{r}_{\mathrm{d}}\right)$ decreases with increasing T .

## 6. Concluding remarks

In the $\mathrm{n}(\mathrm{p})$-type heavily doped InSb -crystal, by using the same physical model, as that given in Eq. (7), and same mathematical methods, as those proposed in I, II and III, and further, by taking into account the corrected values of energy-band-structure parameters, and mainly the correct asymptotic behaviors of the refraction index n and extinction coefficient $\kappa$, as the photon energy $\mathrm{E}(\rightarrow \infty)$, all the numerical results, obtained in III, are now revised and performed.
Then, by basing on our following basic expressions, such as:
(i)the effective static dielectric constant, $\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, due to the impurity size effect, determined by an effective Bohr model [1], and given in Eq. (2),
(ii) the critical donor(acceptor)-density, $\mathrm{N}_{\mathrm{CDn}(\mathrm{NDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, determined from the generalized effective Mott criterion in the MIT, and as given in Eq. (3), being used to determine the effective d(a)-density: $\mathrm{N}^{*} \equiv \mathrm{~N}-$ $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, which gives a physical condition, needed to define the MIT at $\mathrm{T}=0 \mathrm{~K}$, as: $\mathrm{N}^{*} \equiv \mathrm{~N}-$ $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}=0$ or $\mathrm{N}=\mathrm{N}_{\mathrm{CDn}(\mathrm{CDP})}$, noting that $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDP})}$ can also be explained as the density of electrons (holes) localized in the exponential conduction(valence)-band tails (EBT), $\mathrm{N}_{\mathrm{CDn}(\mathrm{CDP})}^{\mathrm{EBT}}$, as that determined in Eq. (21), with a precision of the order of $11 \%$, as observed in Table 1,
(iii) the Fermi energy, $\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{~T}\right)$, determined in Eq. (A3) of the Appendix A, with a precision of the order of $2.11 \times 10^{-4}$ [3], and finally,
(iv) the refraction index n and the extinction coefficient $\kappa$, determined in Equations (28, 29), verifying their correct asymptotic behaviors,
we have investigated the optical coefficients, determined from Equations (24, 25, 28, 29), and their numerical results, given in different physical conditions, have been obtained and discussed in above Tables $2 \mathrm{a}, 2 \mathrm{~b}, 2 \mathrm{c}, 3 \mathrm{a}, 3 \mathrm{~b}, 3 \mathrm{c}, 4 \mathrm{n}(4 \mathrm{p}), 5 \mathrm{n}(5 \mathrm{p})$, and finally $6 \mathrm{n}(6 \mathrm{p})$. In particular, in Tables $3 \mathrm{a}, 3 \mathrm{~b}$ and 3 c , our numerical results for those optical coefficients are found to be more accurate than the corresponding ones, calculated from the FB-PM [11].
Finally, one notes that the MIT occurs in the degenerate case, in which:
(a) $\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}=0, \mathrm{~T}=0\right)=0$, determined by Eq. (A4) of the Appendix A, since it is proportional to $\left(\mathrm{N}^{*}\right)^{2 / 3}$,
(b) as discussed in Eq. (5), in the MIT, in which $\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp} 1)}\left(\mathrm{N}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}=0\right)=\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$, where $\mathbb{E}_{\mathrm{gn} 1(\mathrm{gp1} 1)}$ and $\mathbb{E}_{\mathrm{gni}(\mathrm{Fgpi})}$ are the optical band gap and intrinsic band gap, respectively, and c) as discussed in Section 5.1, as $E=E_{\text {CPE }}\left(r_{d(a)}\right) \equiv \mathbb{E}_{\text {gni }}(\operatorname{gpi})\left(r_{d(a)}\right)$ or the effective photon energy $E^{*} \equiv$ $\mathrm{E}-\mathbb{E}_{\mathrm{gni}(\mathrm{gpi})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, one has: $\kappa\left(\mathrm{E}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0, \varepsilon_{2}\left(\mathrm{E}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0, \sigma_{0}\left(\mathrm{E}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$ and $\alpha\left(\mathrm{E}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, according also to the MIT-case, being new results.

In summary, all the numerical results, given in III [3], are now revised and performed in the present work.

## Appendix

## Appendix A. Fermi Energy and generalized Einstein relation

A1. In the $n(p)$-type InSb-crystals, the Fermi energy $\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})} \equiv\left[\mathbb{E}_{\mathrm{fn}}-\mathbb{E}_{\mathrm{c}}\right]\left(\mathbb{E}_{\mathrm{Fp}} \equiv\left[\mathbb{E}_{\mathrm{v}}-\mathbb{E}_{\mathrm{fp}}\right]\right), \mathbb{E}_{\mathrm{c}(\mathrm{v})}$ being the conduction (valence) band edges, obtained for any T and donor (acceptor) density N , being investigated in our previous paper, with a precision of the order of $2.11 \times 10^{-4}$ [3], is now summarized in the following. In this work, N is replaced by the effective density $\mathrm{N}^{*}, \mathrm{~N}^{*} \equiv \mathrm{~N}-\mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right), \mathrm{N}_{\mathrm{CDn}(\mathrm{CDp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)$ being the critical density, being characteristic of the MIT-phenomenon, and their numerical results are given in Table 1, meaning that $\mathrm{N}^{*}=0$ at this transition.
First, we define the reduced electron density by:
$\mathrm{u}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right) \equiv \frac{\mathrm{N}^{*}}{\mathrm{~N}_{\mathrm{c}(\mathrm{v})}}, \mathrm{N}_{\mathrm{c}(\mathrm{v})}(\mathrm{T})=2 \times \mathrm{g}_{\mathrm{c}(\mathrm{v})} \times\left(\frac{\mathrm{m}_{\mathrm{n}(\mathrm{p}}^{*} \times \mathrm{K}_{\mathrm{B}} \mathrm{T}}{2 h^{2}}\right)^{\frac{3}{2}}\left(\mathrm{~cm}^{-3}\right)$,
where $N_{c(v)}(T)$ is the conduction (valence)-band density of states, the values of $g_{c(v)}=1(1)$, and $m_{n(p)}^{*} / m_{0}$, defined in Section 2, can be equal to : $m_{n(p)} / m_{o}=0.015$ (0.39), and to $m_{r} / m_{o}=\frac{m_{n} \times m_{p}}{m_{n}+m_{p}}=0.014444$. In particular, as used in Section 3 for determining the optical band gap in degenerate InSb-crystals, $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*}$ / $m_{0}=m_{r} / m_{o}=0.014444$ was chosen. Therefore, from Eq. (A1), $N_{c}=N_{v}$, and thus $u\left(N^{*}, r_{d}, T\right)=$ $\mathrm{u}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{a}}, \mathrm{T}\right) \equiv u$.
Then, the reduced Fermi energy in the $\mathrm{n}(\mathrm{p})$-type InSb crystals is determined by:
$\frac{\mathbb{E}_{\mathrm{Fn}^{2}(\mathrm{Fp})}(\mathrm{u})}{\mathrm{k}_{\mathrm{B}} \mathrm{T}}\left(\frac{\mathbb{E}_{\mathrm{Fp}}(\mathrm{u})}{\mathrm{k}_{\mathrm{B}} \mathrm{T}}\right)=\frac{\mathrm{G}(\mathrm{u})+\mathrm{Au}^{\mathrm{B}} \mathrm{F}(\mathrm{u})}{1+\mathrm{Au}^{\mathrm{B}}}=\theta_{\mathrm{n}}(\mathrm{u}) \equiv \frac{\mathrm{V}(\mathrm{u})}{\mathrm{W}(u)}, \mathrm{A}=0.0005372$ and $\mathrm{B}=4.82842262$,
where $\mathrm{F}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right)=\mathrm{au}^{\frac{2}{3}}\left(1+\mathrm{bu}^{-\frac{4}{3}}+\mathrm{cu}^{-\frac{8}{3}}\right)^{-\frac{2}{3}}$, obtained for $\mathrm{u} \gg 1$, according to the degenerate cas, $\mathrm{a}=[(3 \sqrt{\pi} / 4)]^{2 / 3}, \quad \mathrm{~b}=\frac{1}{8}\left(\frac{\pi}{a}\right)^{2}, \mathrm{c}=\frac{62.3739855}{1920}\left(\frac{\pi}{a}\right)^{4}$, and then $\mathrm{G}(\mathrm{u}) \simeq \operatorname{Ln}(\mathrm{u})+2^{-\frac{3}{2}} \times \mathrm{u} \times \mathrm{e}^{-\mathrm{du}}$ for $\mathrm{u} \ll$ 1, according to the non - degenerate case, with: $\quad d=2^{3 / 2}\left[\frac{1}{\sqrt{27}}-\frac{3}{16}\right]>0$. As noted above, one has: $\mathbb{E}_{\mathrm{Fn}}(\mathrm{u})=\mathbb{E}_{\mathrm{Fp}}(\mathrm{u})$, in the this $\mathrm{d}(\mathrm{a})$-InSb systems.
So, in the degenerate case ( $u \gg 1$ ), one has:
$\mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}, \mathrm{T}\right) \equiv \mathbb{E}_{\mathrm{Fn}(\mathrm{Fp})}\left(\mathrm{N}^{*}, \mathrm{~T}\right)=\mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}(\mathrm{u}) \times\left(1+\mathrm{bu}^{-\frac{4}{3}}+\mathrm{cu}^{-\frac{8}{3}}\right)^{-\frac{2}{3}}$.
Then, at $T=0 K$, since $u^{-1}=0$, Eq. (A. 3 ) is reduced to:
$\mathbb{E}_{\text {Fno }(\mathrm{Fpo})}\left(\mathrm{N}^{*}\right) \equiv \frac{\hbar^{2} \times \mathrm{k}_{\mathrm{Ff}(\mathrm{Fp})}^{2}\left(\mathrm{~N}^{*}\right)}{2 \times \mathrm{m}_{\mathrm{r}}}$,
being proportional to $\left(\mathrm{N}^{*}\right)^{2 / 3}$, and equal to $0, \mathbb{E}_{\mathrm{Fno}(\mathrm{Fpo})}\left(\mathrm{N}^{*}=0\right)=0$, according to the MIT, as discussed in Section 2 and 3.

## Appendix B. Approximate forms for band gap narrowing (BGN)

First of all, in the $n(p)$-type $\operatorname{InSb}$-crystals, we define the effective reduced Wigner-Seitz radius $\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}$, characteristic of the interactions, by:
$\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right) \equiv\left(\frac{3 \mathrm{~g}_{\mathrm{c}}(\mathrm{v})}{4 \pi \mathrm{~N}^{*}}\right)^{1 / 3} \times \frac{1}{\mathrm{a}_{\mathrm{Bn}(\mathrm{Bp})}\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)}=1.1723 \times 10^{8} \times\left(\frac{\mathrm{g}_{\mathrm{c}(\mathrm{v})}}{\mathrm{N}^{*}}\right)^{1 / 3} \times \frac{\mathrm{m}_{\mathrm{n}(\mathrm{p}}^{*} / \mathrm{m}_{\mathrm{o}}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)}$.
In particular, in the following, $\mathrm{m}_{\mathrm{n}(\mathrm{p})}^{*} / \mathrm{m}_{\mathrm{o}}=\mathrm{m}_{\mathrm{r}} / \mathrm{m}_{0}$, is taken for evaluating the band gap narrowing (BGN), as used in Section 3. Therefore, the correlation energy of an effective electron gas, $\mathbb{E}_{\mathrm{CE}}\left(\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}\right)$, is found to be given by [1]:
$\mathbb{E}_{\mathrm{CE}}\left(\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}\right) \equiv \mathbb{E}_{\text {CE }}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=\frac{-0.87553}{0.0908+\mathrm{r}_{\text {sn }}(\mathrm{sp})}+\frac{\frac{0.87553}{0.0908+\mathrm{r}_{\text {sn( }(\mathrm{sp})}}+\left(\frac{2[1-\ln (2)]}{\mathrm{n}^{2}}\right) \times \ln \left(\mathrm{r}_{\mathrm{sn}(\mathrm{sp})}\right)-0.093288}{1+0.03847728 \times \mathrm{r}_{\mathrm{sn}(\mathrm{sp})}^{1.678876}}$.
Then, the band gap narrowing (BGN) can be determined by [1]:
$\Delta \mathbb{E}_{\mathrm{gn}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{d}}\right) \simeq \mathrm{a}_{1} \times \frac{\varepsilon_{\mathrm{sb}}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}}\right)} \times \mathrm{N}_{\mathrm{r}}^{1 / 3}+\mathrm{a}_{2} \times \frac{\varepsilon_{\mathrm{sb}}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}}\right)} \times \mathrm{N}_{\mathrm{r}}^{\frac{1}{3}} \times\left(2.503 \times\left[-\mathbb{E}_{\mathrm{CE}}\left(\mathrm{r}_{\mathrm{sn}}\right) \times \mathrm{r}_{\mathrm{sn}}\right]\right)+\mathrm{a}_{3} \times\left[\frac{\varepsilon_{\mathrm{sb}}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}}\right]}\right]^{5 / 4} \times \sqrt{\frac{m_{\mathrm{p}}}{m_{\mathrm{r}}}} \times$ $\mathrm{N}_{\mathrm{r}}^{1 / 4}+\mathrm{a}_{4} \times \sqrt{\sqrt{\frac{\varepsilon_{\mathrm{s}}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}}\right)}}} \times \mathrm{N}_{\mathrm{r}}^{1 / 2} \times 2+\mathrm{a}_{5} \times\left[\frac{\varepsilon_{\mathrm{s}}}{\varepsilon\left(\mathrm{r}_{\mathrm{d}}\right)}\right]^{\frac{3}{2}} \times \mathrm{N}_{\mathrm{r}}^{\frac{1}{6}}, \mathrm{~N}_{\mathrm{r}} \equiv \frac{\mathrm{N}^{*}=\mathrm{N}-\mathrm{N}_{\mathrm{cDn}}\left(\mathrm{r}_{\mathrm{r}}\right)}{9.999 \times 10^{17} \mathrm{~cm}^{-3}}$,
and
$\Delta \mathbb{E}_{\mathrm{gp}}\left(\mathrm{N}^{*}, \mathrm{r}_{\mathrm{a}}\right) \simeq \mathrm{a}_{1} \times \frac{\varepsilon_{\mathrm{ln}}}{\varepsilon\left(r_{\mathrm{ra}}\right)} \times N_{\mathrm{r}}^{1 / 3}+\mathrm{a}_{2} \times \frac{\varepsilon_{\mathrm{ln}}}{\varepsilon\left(r_{\mathrm{a}}\right)} \times N_{\mathrm{r}}^{\frac{1}{3}} \times\left(2.503 \times\left[-\mathbb{E}_{\mathrm{CE}}\left(\mathrm{r}_{\mathrm{sp}}\right) \times \mathrm{r}_{\mathrm{sp}}\right]\right)+\mathrm{a}_{3} \times\left[\frac{\varepsilon_{\mathrm{ln}}}{\varepsilon\left(\mathrm{r}_{\mathrm{a}}\right.}\right]^{5 / 4} \times \sqrt{\frac{m_{\mathrm{n}}}{m_{\mathrm{r}}}} \times$ $\mathrm{N}_{\mathrm{r}}^{1 / 4}+2 \mathrm{a}_{4} \times \sqrt{\frac{\varepsilon_{\mathrm{ln}}}{\varepsilon\left(\mathrm{r}_{\mathrm{a}}\right)}} \times \mathrm{N}_{\mathrm{r}}^{1 / 2}+\mathrm{a}_{5} \times\left[\frac{\varepsilon_{\mathrm{ln}}}{\varepsilon\left(\mathrm{r}_{\mathrm{a}}\right)}\right]^{\frac{3}{2}} \times \mathrm{N}_{\mathrm{r}}^{\frac{1}{6}}, \quad \mathrm{~N}_{\mathrm{r}} \equiv\left(\frac{\mathrm{N}^{*}=\mathrm{N}-\mathrm{N}_{\mathrm{CDD}}\left(\mathrm{r}_{\mathrm{a}}\right)}{9.999 \times 10^{17} \mathrm{~cm}^{-3}}\right)$,
Here, $\varepsilon_{\text {Sb }}=\varepsilon_{\text {In }}=16.8, \mathrm{a}_{1}=3.80 \times 10^{-3}(\mathrm{eV}), \mathrm{a}_{2}=6.5 \times 10^{-4}(\mathrm{eV}), \mathrm{a}_{3}=2.85 \times 10^{-3}(\mathrm{eV}), \mathrm{a}_{4}=$ $5.597 \times 10^{-3}(\mathrm{eV})$ and $\mathrm{a}_{5}=8.1 \times 10^{-4}(\mathrm{eV})$.
Therefore, in Equations (B3, B4), at $T=0 \mathrm{~K}$ and $\mathrm{N}^{*}=0$, and for any $\mathrm{r}_{\mathrm{d}(\mathrm{a})}, \Delta \mathbb{E}_{\mathrm{gn}(\mathrm{gp})}\left(\mathrm{N}^{*}=0, \mathrm{r}_{\mathrm{d}(\mathrm{a})}\right)=0$, according to the metal-insulator transition (MIT).
